# RESONANCES AND SPECTRAL SHIFT FUNCTION NEAR THE LANDAU LEVELS 

by Jean-François BONY, Vincent BRUNEAU \& Georgi RAIKOV

Abstract. - We consider the 3D Schrödinger operator $H=H_{0}+V$ where $H_{0}=(-i \nabla-A)^{2}-b, A$ is a magnetic potential generating a constant magneticfield of strength $b>0$, and $V$ is a short-range electric potential which decays superexponentially with respect to the variable along the magnetic field. We show that the resolvent of $H$ admits a meromorphic extension from the upper half plane to an appropriate Riemann surface $\mathcal{M}$, and define the resonances of $H$ as the poles of this meromorphic extension. We study their distribution near any fixed Landau level $2 b q, q \in \mathbb{N}$. First, we obtain a sharp upper bound of the number of resonances in a vicinity of $2 b q$. Moreover, under appropriate hypotheses, we establish corresponding lower bounds which imply the existence of an infinite number of resonances, or the absence of resonances in certain sectors adjoining $2 b q$. Finally, we deduce a representation of the derivative of the spectral shift function (SSF) for the operator pair $\left(H, H_{0}\right)$ as a sum of a harmonic measure related to the resonances, and the imaginary part of a holomorphic function. This representation justifies the Breit-Wigner approximation, implies a trace formula, and provides information on the singularities of the SSF at the Landau levels.

Résumé. - On étudie l'opérateur de Schrödinger magnétique en dimension 3, $H=H_{0}+V$ où $H_{0}=(-i \nabla-A)^{2}-b, A$ est un potentiel magnétique générant un champ magnétique constant de force $b>0$ fixée et $V$ est un potentiel électrique qui décroît super-exponentiellement dans la direction du champ magnétique. On montre que la résolvante de $H$ admet un prolongement méromorphe du plan supérieur une certaine surface de Riemann $\mathcal{M}$ et on définit les résonances de $H$ comme les pôles de cette extension méromorphe. On étudie leur répartition près d'un niveau de Landau fixé $2 b q, q \in \mathbb{N}$. On obtient d'abord des majorations du nombre de résonances dans des petits domaines proches de $2 b q$. Sous des hypothses supplémentaires, on prouve des minorations du nombre de résonances qui implique la présence d'une infinité de résonances ou bien l'absence de résonances dans certains secteurs de sommet $2 b q$. Finalement, on montre que la fonction de décalage spectral (FDS) associée à la paire ( $H, H_{0}$ ) est la somme de mesures harmoniques associées aux résonances et de la partie imaginaire d'une fonction holomorphe. Cette formule justifie l'approximation de Breit-Wigner, implique une formule de trace à la Sjöstrand et donne des informations sur les singularités de la FDS aux niveaux de Landau.

Keywords: Magnetic Schrödinger operators, resonances, spectral shift function, BreitWigner approximation.
Math. classification: 35P25, 35J10, 47F05, 81Q10.

## 1. Introduction

Let

$$
H_{0}:=\left(D_{x_{1}}+\frac{1}{2} b x_{2}\right)^{2}+\left(D_{x_{2}}-\frac{1}{2} b x_{1}\right)^{2}-b+D_{x_{3}}^{2}, \quad D_{\nu}:=-i \frac{\partial}{\partial \nu}
$$

be the Schrödinger operator with homogeneous magnetic field of strength $b>0$, pointing at the $x_{3}$-direction. Initially, the self-adjoint operator $H_{0}$ is defined on $C_{0}^{\infty}\left(\mathbb{R}^{3}\right)$, and then is closed in $L^{2}\left(\mathbb{R}^{3}\right)$. This operator can be written in $L^{2}\left(\mathbb{R}^{3}\right)=L^{2}\left(\mathbb{R}^{2}\right) \otimes L^{2}(\mathbb{R})$ as

$$
H_{0}=H_{0, \perp} \otimes I+I \otimes D_{x_{3}}^{2}
$$

with $H_{0, \perp}=\left(D_{x_{1}}+\frac{1}{2} b x_{2}\right)^{2}+\left(D_{x_{2}}-\frac{1}{2} b x_{1}\right)^{2}-b$.
It is well known that the spectrum of the operator $H_{0, \perp}$ consists of the Landau levels $2 q b, q \in \mathbb{N}:=\{0,1 \ldots\}$, and the multiplicity of each eigenvalue $2 b q$ is infinite (see e.g. [1]). Consequently, the spectrum of $H_{0}$ is absolutely continuous, equals $[0,+\infty[$, and has an infinite set of thresholds $2 q b, q \geqslant 0$.

For $\mathbf{x}=\left(x_{1}, x_{2}, x_{3}\right) \in \mathbb{R}^{3}$ we denote by $X_{\perp}=\left(x_{1}, x_{2}\right)$ the variables on the plane perpendicular to the magnetic field. We assume that the electric potential $V: \mathbb{R}^{3} \rightarrow \mathbb{R}$ is Lebesgue measurable, and satisfies the estimates

$$
\begin{equation*}
V(\mathbf{x})=\mathcal{O}\left(\left\langle X_{\perp}\right\rangle^{-m_{\perp}}\left\langle x_{3}\right\rangle^{-m_{3}}\right), \quad \mathbf{x} \in \mathbb{R}^{3}, \tag{1.1}
\end{equation*}
$$

with $m_{\perp}>2, m_{3}>1$, and $\langle x\rangle:=\left(1+|x|^{2}\right)^{1 / 2}, x \in \mathbb{R}^{d}, d \geqslant 1$.
On the domain of $H_{0}$ we introduce the operator $H:=H_{0}+V$. Since $V$ is a relatively compact perturbation of $H_{0}$, it follows from the Weyl criterion that the essential spectra of $H$ and $H_{0}$ are the same. Moreover, since $V$ is a relatively trace-class perturbation, the Kuroda-Birman theorem implies that the absolutely continuous spectrum coincides with $[0,+\infty[$.

It is well known that $H$ can have infinite negative discrete spectrum and, for some special $V$, it can have infinitely many embedded eigenvalues below each Landau level (see [1], [23] or [24]). On the other hand, it is shown in [11] that in the case of sign-definite $V$, the spectral shift function (SSF) for the operator pair $\left(H, H_{0}\right)$ has a singularity at each Landau level. Therefore, it is natural to expect that there could be accumulation of the resonances of the operator $H$ near the Landau levels. For a Coulomb potential, some numerical results confirm this conjecture [8]. The goal of this paper is to study the resonances near the Landau levels, and to establish the link between these resonances and the spectral shift function by the so-called Breit-Wigner approximation. Such a representation of the derivative of the spectral shift function related to the resonances, implies
trace formulas which have given recently a substantial impetus to the research concerning the upper and lower bounds of the number of resonances in different situations (see [26], [28], [27], [29], [21], [3], [6], [10]).

We consider potentials $V$ which decay super-exponentially with respect to $x_{3}$ (or are compactly supported with respect to $x_{3}$ ). Hence, we do not use dilation methods in order to define the resonances near the Landau levels. For a definition using complex dilation, we refer the reader to [31], [14] where precise asymptotics as $b \rightarrow \infty$ of the resonances near the real axis is given. In our work, $b$ is fixed, and we study the number of resonances in a domain $2 b q+r \Omega$ as $r$ tends to 0 . Then we justify the Breit-Wigner approximation for the spectral shift function near the Landau levels.

The paper is organized as follows. In the next section, we define the resonances as the poles of the resolvent, the first step being to introduce a Riemann surface to which the resolvent is extended. Note that the resonances defined as poles of the resolvent, are also zeros of a generalized Krein perturbation determinant with the same multiplicity. In Section 3, we obtain an upper bound of the number of resonances in a domain $2 b q+r \Omega$ as $r$ tends to 0 (see Theorem 1). In Section 4, we obtain more information on the localization of the resonances for the case of perturbations of definite sign. In particular, we show that there is an infinite number of resonances near any arbitrary fixed Landau level for small $V$ of sufficiently rapid decay (see Theorem 2), and that there are no embedded eigenvalues for small non-negative $V$ (see Proposition 7). At last, in Section 5, we represent the derivative of the spectral shift function near the Landau levels as a sum of a harmonic measure related to the resonances and the imaginary part of a holomorphic function (see Theorem 3). Such a representation justifies the Breit-Wigner approximation, implies a trace formula, and for a special class of $V$ sufficiently slowly decaying with respect to the variables perpendicular to the magnetic field, allows us to estimate the remainder in the asymptotic relations obtained in [11].

## 2. Resonances

In this section we define the resonances of $H=H_{0}+V$ for $V$ decaying super-exponentially with respect to $x_{3}$, i.e.

$$
\begin{equation*}
V(\mathbf{x})=\mathcal{O}\left(\left\langle X_{\perp}\right\rangle^{-m_{\perp}} \exp \left(-N\left|x_{3}\right|\right)\right) \tag{2.1}
\end{equation*}
$$

for $m_{\perp} \geqslant 0$ and any $N>0$. As in [2], the resonances will be defined as the poles of the meromorphic continuation of the resolvent in some weighted $L^{2}$
spaces. Since $V$ is not compactly supported with respect to $x_{3}$, the cut-off resolvent cannot be used here.

First, we have to prove the existence of a holomorphic extension for the unperturbed operator. Let $\mathbb{C}_{+}:=\{\lambda \in \mathbb{C} ; \operatorname{Im} \lambda>0\}$ be the open upper half plane. For $\lambda \in \mathbb{C}_{+}$we have

$$
\begin{equation*}
\left(H_{0}-\lambda\right)^{-1}=\sum_{q \in \mathbb{N}} p_{q} \otimes\left(D_{x_{3}}^{2}+2 b q-\lambda\right)^{-1} \tag{2.2}
\end{equation*}
$$

where $p_{q}$ is the orthogonal projection onto $\mathcal{H}_{q}:=\operatorname{ker}\left(H_{0, \perp}-2 b q\right)$.
Let us recall that for $\operatorname{Im} k>0$, the integral kernel of the operator $\left(D_{x_{3}}^{2}-k^{2}\right)^{-1}$ is given by

$$
\begin{equation*}
\mathcal{R}\left(x_{3}, x_{3}^{\prime}\right)=\frac{i \mathrm{e}^{i k\left|x_{3}-x_{3}^{\prime}\right|}}{2 k} \tag{2.3}
\end{equation*}
$$

Then, for $N>0$, the operator-valued function

$$
\begin{equation*}
t_{N}\left(k^{2}\right):=\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}^{2}-k^{2}\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}^{\prime}\right\rangle} \in \mathcal{L}\left(L^{2}\left(\mathbb{R}_{x_{3}}\right), H^{2}\left(\mathbb{R}_{x_{3}}\right)\right) \tag{2.4}
\end{equation*}
$$

can be extended holomorphically from $\mathbb{C}_{+}$to $\left\{k \in \mathbb{C}^{*} ; \operatorname{Im} k>-N\right\}$. Hence, for any $N>0$ and $q \in \mathbb{N}$,

$$
z \longmapsto\left(D_{x_{3}}^{2}+2 b q-z\right)^{-1} \in \mathcal{L}\left(\mathrm{e}^{-N\left\langle x_{3}\right\rangle} L^{2}\left(\mathbb{R}_{x_{3}}\right), \mathrm{e}^{N\left\langle x_{3}\right\rangle} H^{2}\left(\mathbb{R}_{x_{3}}\right)\right)
$$

has a holomorphic extension from $\mathbb{C} \backslash[2 b q,+\infty[$ to the 2-sheeted covering

$$
\pi_{q}: k \in \mathbb{C}^{*} \longmapsto k^{2}+2 b q \in \mathbb{C} \backslash\{2 b q\}
$$

(with $\operatorname{Im} k>-N$ ). However, this covering depends on $q$, and therefore it is not suitable for the extension of (2.2).

A natural domain of analytic extension of (2.2) is the universal covering of $\mathbb{C} \backslash 2 b \mathbb{N}$ :

$$
\bar{\pi}: \overline{\mathbb{C} \backslash 2 b \mathbb{N}} \longrightarrow \mathbb{C} \backslash 2 b \mathbb{N}
$$

but it does not give a maximal analytic continuation. Indeed for some $z \in \mathbb{C} \backslash 2 b \mathbb{N}$, there are some points $z_{1}, z_{2} \in \bar{\pi}^{-1}(z), z_{1} \neq z_{2}$ such that the germs of $\left(H_{0}-z\right)^{-1}$ at $z_{1}$ and at $z_{2}$ are the same. Next, we introduce the equivalence relation $\mathcal{R}$ concerning such pairs of points $\left(z_{1}, z_{2}\right)$. Let $\pi_{1}(\mathbb{C} \backslash 2 b \mathbb{N})$ be the fundamental group of $\mathbb{C} \backslash 2 b \mathbb{N}$, and $G$ be its subgroup generated by $\left\{a_{1}^{2}, a_{2} a_{1} a_{2}^{-1} a_{1}^{-1}\right.$; with $\left.a_{1}, a_{2} \in \pi_{1}(\mathbb{C} \backslash 2 b \mathbb{N})\right\}$. We will write $z_{1} \mathcal{R} z_{2}$ if $\bar{\pi} z_{1}=\bar{\pi} z_{2}$, and for any path $\gamma$ connecting $z_{1}$ with $z_{2}$, the class of the closed path $\pi \gamma$ in $\pi_{1}(\mathbb{C} \backslash 2 b \mathbb{N})$ is an element of $G$ (that is $\pi(\gamma)$ goes an even number of times round each Landau level).

Then we define the domain $\mathcal{M}$ of the analytic extension of $\left(H_{0}-z\right)^{-1}$, or equivalently of the whole set of square roots $\sqrt{z-2 b q}, q \in \mathbb{N}$, as the quotient of $\overline{\mathbb{C} \backslash 2 b \mathbb{N}}$ by the relation $\mathcal{R}$. This domain can also be identified
with the following covering of $\mathbb{C} \backslash 2 b \mathbb{N}$ (see for instance Proposition 13.23 of [15]):

Definition 1. - Let $\pi_{1}(\mathbb{C} \backslash 2 b \mathbb{N})$ be the fundamental group of $\mathbb{C} \backslash 2 b \mathbb{N}$. Let $G$ be the subgroup of $\pi_{1}(\mathbb{C} \backslash 2 b \mathbb{N})$ generated by

$$
\left\{a_{1}^{2}, a_{2} a_{1} a_{2}^{-1} a_{1}^{-1} ; \text { with } a_{1}, a_{2} \in \pi_{1}(\mathbb{C} \backslash 2 b \mathbb{N})\right\} .
$$

We define $\pi_{G}: \mathcal{M} \rightarrow \mathbb{C} \backslash 2 b \mathbb{N}$ as the connected infinite-sheeted covering such that $\pi_{1}(\mathcal{M})=G$.

From now on, we fix a base point in $\mathcal{M}$, and define the physical plane $\mathcal{F}$ as the connected component of $\pi_{G}^{-1}(\mathbb{C} \backslash[0,+\infty[)$ containing this base point. By definition, the functions $\mathcal{M} \ni z \mapsto \sqrt{z-2 b q}$ have a positive imaginary part on $\mathcal{F}$. Let $\mathcal{F}_{+}=\mathcal{F} \cap \pi_{G}^{-1}\left(\mathbb{C}_{+}\right)$be the upper half-plane. In what follows, we identify $\mathcal{F}$ (resp. $\mathcal{F}_{+}$and $\partial \mathcal{F}_{+}$) with $\mathbb{C} \backslash\left[0,+\infty\left[\left(\right.\right.\right.$ resp. $\mathbb{C}_{+}$and $\mathbb{R} \backslash 2 b \mathbb{N}$ ), and denote by $z$ the generic point on $\mathcal{M}$.

For $\lambda_{0} \in \mathbb{C}$ and $\varepsilon>0$ put

$$
\begin{aligned}
D\left(\lambda_{0}, \varepsilon\right) & :=\left\{\lambda \in \mathbb{C} ;\left|\lambda-\lambda_{0}\right|<\varepsilon\right\} \\
D\left(\lambda_{0}, \varepsilon\right)^{*} & :=\left\{\lambda \in \mathbb{C} ; 0<\left|\lambda-\lambda_{0}\right|<\varepsilon\right\}
\end{aligned}
$$

Definition 2. - We denote by $D_{q}^{*} \subset \mathcal{M}$, the connected component of $\pi_{G}^{-1}\left(D(2 b q, 2 b)^{*}\right)$ that intersects $\mathcal{F}_{+}$.

Since $\pi_{G}: D_{q}^{*} \rightarrow D(2 b q, 2 b)^{*}$ is a 2-sheeted covering of $D(2 b q, 2 b)^{*}$, there exists an analytic bijection

$$
\begin{equation*}
z_{q}: k \in D(0, \sqrt{2 b})^{*} \longrightarrow z_{q}(k) \in D_{q}^{*} \tag{2.5}
\end{equation*}
$$

such that $\pi_{G}\left(z_{q}(k)\right)=2 b q+k^{2}$ and $z_{q}^{-1}\left(D_{q}^{*} \cap \mathcal{F}_{+}\right)$is the first quadrant of $D(0, \sqrt{2 b})^{*}$.

For $N>0$, we denote by $\mathcal{M}_{N}$ the set of points $z \in \mathcal{M}$ such that for each $q \in \mathbb{N}$, we have $\operatorname{Im} \sqrt{z-2 b q}>-N$. Of course, we have $\bigcup_{N>0} \mathcal{M}_{N}=\mathcal{M}$.

Figure 2.1 summarizes the setting near the Landau level $2 b q$. For the free operator, we have the following

Proposition 1. - For each $N>0$ the operator

$$
\left(H_{0}-z\right)^{-1}: \mathrm{e}^{-N\left\langle x_{3}\right\rangle} L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right) \longrightarrow \mathrm{e}^{N\left\langle x_{3}\right\rangle} L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right)
$$

has a holomorphic extension from the open upper half plane to $\mathcal{M}_{N}$. We denote its holomorphic extension by $R_{0}(z)$.

Moreover, for $N>0$ and $v_{\perp}\left(X_{\perp}\right)=\left\langle X_{\perp}\right\rangle^{-\alpha}, \alpha>1$, the holomorphic extension of

$$
T_{v_{\perp}}: z \longmapsto v_{\perp}\left(X_{\perp}\right) \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(H_{0}-z\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}
$$

Figure 2.1. Pre-images under $z_{q}$
is holomorphic on $\mathcal{M}_{N}$ with values in the Hilbert-Schmidt class $S_{2}$ on $L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right)$.
Proof. - Since the kernel of $t_{N}\left(k^{2}\right)$ is given by

$$
\mathrm{e}^{-N\left\langle x_{3}\right\rangle} \frac{i \mathrm{e}^{i k\left|x_{3}-x_{3}^{\prime}\right|}}{2 k} \mathrm{e}^{-N\left\langle x_{3}^{\prime}\right\rangle},
$$

the operator-valued function $k \mapsto t_{N}\left(k^{2}\right)$ has a holomorphic extension from $\mathbb{C}_{+}$to $\left\{k \in \mathbb{C}^{*} ; \operatorname{Im} k>-N\right\}$ in the Hilbert-Schmidt class $S_{2}$ and in the trace class $S_{1}$ (see for instance [13]). For $\operatorname{Im} k>0$, we have the trace-class estimate

$$
\begin{align*}
\left\|t_{N}\left(k^{2}\right)\right\|_{1} & \leqslant\left\|\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}-k\right)^{-1}\right\|_{2} \cdot\left\|\left(D_{x_{3}}+k\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\right\|_{2}  \tag{2.6}\\
& \leqslant \frac{1}{2 \pi N} \int_{\mathbb{R}} \frac{\mathrm{d} \eta}{\eta^{2}+|\operatorname{Im} k|^{2}}=\mathcal{O}\left(|\operatorname{Im} k|^{-1}\right)
\end{align*}
$$

and when moreover $\operatorname{Re} k^{2}<0$, we have the Hilbert-Schmidt estimate

$$
\begin{align*}
\left\|t_{N}\left(k^{2}\right)\right\|_{2}^{2} & =\operatorname{tr}\left(\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}^{2}-k^{2}\right)^{-1}\left(D_{x_{3}}^{2}-\bar{k}^{2}\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\right)  \tag{2.7}\\
& \leqslant \frac{1}{2 \pi N} \int_{\mathbb{R}} \frac{\mathrm{d} \eta}{\left(\eta^{2}+\left|\operatorname{Re} k^{2}\right|\right)^{2}}=\mathcal{O}\left(\left|\operatorname{Re} k^{2}\right|^{-\frac{3}{2}}\right)
\end{align*}
$$

where $\|\cdot\|_{j}$ stands for the norm in $S_{j}, j=1,2$.
By the definition of $\mathcal{M}_{N}$, it follows that for any $q \in \mathbb{N}$, the operatorvalued function $z \mapsto \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}^{2}-z+2 b q\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle} \in S_{1}$ can be holomorphically extended from $\mathcal{F}_{+}$to $\mathcal{M}_{N}$. We denote its holomorphic extension to $\mathcal{M}_{N}$ also by $t_{N}(z-2 b q)$. Since $\left\{p_{q} ; q \in \mathbb{N}\right\}$ is a family of orthogonal projectors, we deduce the holomorphic extension of (2.2).

Now, let us prove the existence of a holomorphic extension of $T_{v_{\perp}}$ in the Hilbert-Schmidt class. Let $z_{0} \in \mathcal{M}_{N}$ be fixed, and $\Omega_{0}$ be a relatively compact neighborhood of $z_{0}$. Since any path on $\mathcal{M}_{N}$ can enclose only a
finite number of Landau levels, there exists $q_{0}$ sufficiently large (depending of $\left.\Omega_{0}\right)$ such that $q \geqslant q_{0}$ implies

$$
t_{N}(z-2 b q)=\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}^{2}-z+2 b q\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle} .
$$

Then for $q \geqslant q_{0}$ we have $\left\|t_{N}(z-2 b q)\right\|=\mathcal{O}\left(\langle q\rangle^{-1}\right)$, and furthermore, it follows from (2.7) that the identity

$$
\begin{align*}
\left\|t_{N}(z-2 b q)\right\|_{2} & =\left\|\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}^{2}-z+2 b q\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\right\|_{2}  \tag{2.8}\\
& =\mathcal{O}\left(\langle q\rangle^{-\frac{3}{4}}\right)
\end{align*}
$$

holds for any $q \geqslant q_{0}$, uniformly with respect to $z \in \Omega_{0}$.
Next, we have

$$
\begin{equation*}
T_{v_{\perp}}(z)=\sum_{q=0}^{q_{0}} v_{\perp} p_{q} \otimes t_{N}(z-2 b q)+\sum_{q>q_{0}} v_{\perp} p_{q} \otimes t_{N}(z-2 b q) \tag{2.9}
\end{equation*}
$$

where $q_{0}$ is chosen as above. It is well known (see [20]) that the orthogonal projection $p_{q}$ admits an explicit integral kernel

$$
\mathcal{P}_{q, b}\left(X_{\perp}, X_{\perp}^{\prime}\right)=\frac{b}{2 \pi} L_{q}\left(\frac{b\left|X_{\perp}-X_{\perp}^{\prime}\right|^{2}}{2}\right)
$$

$$
\begin{equation*}
\times \exp \left(-\frac{1}{4} b\left(\left|X_{\perp}-X_{\perp}^{\prime}\right|^{2}+2 i\left(x_{1} x_{2}^{\prime}-x_{1}^{\prime} x_{2}\right)\right)\right) \tag{2.10}
\end{equation*}
$$

where $L_{q}(t):=\left(\mathrm{e}^{t} / q!\right) \mathrm{d}^{q}\left(t^{q} \mathrm{e}^{-t}\right) / \mathrm{d} t^{q}$ are the Laguerre polynomials. Note that $\mathcal{P}_{q, b}$ is constant onto the diagonal, i.e.

$$
\mathcal{P}_{q, b}\left(X_{\perp}, X_{\perp}\right)=\frac{b}{2 \pi}, \quad X_{\perp} \in \mathbb{R}^{2}
$$

Further, if $U \in L^{r}\left(\mathbb{R}^{2}\right), r \geqslant 1$, then $p_{q} U p_{q}$ is in the Schatten-von Neumann class $S_{r}$ (see Lemma 5.1 of [22]). In particular, $p_{q} v_{\perp}^{2} p_{q} \in S_{1}$, and hence $v_{\perp} p_{q} v_{\perp} \in S_{1}$, and $v_{\perp} p_{q} \in S_{2}$ with

$$
\left\|v_{\perp} p_{q}\right\|_{2}^{2}=\operatorname{tr}\left(v_{\perp} p_{q} v_{\perp}\right)=\frac{b}{2 \pi} \int_{\mathbb{R}^{2}} v_{\perp}\left(X_{\perp}\right)^{2} \mathrm{~d} X_{\perp}
$$

which is uniform with respect to $q$. Combining this with (2.8) and $p_{q} p_{k}=$ $\delta_{q, k} p_{q}$, we deduce that the infinite sum in (2.9) is convergent in $S_{2}$, and hence $z \mapsto T_{v_{\perp}}(z) \in S_{2}$ has a holomorphic extension to $\mathcal{M}_{N}$. This concludes the proof of Proposition 1.

For further references we formulate the following lemma which complements Proposition 1.

Lemma 1. - For $V$ satisfying (2.1) with $m_{\perp}>2$, the operator

$$
\mathcal{F}_{+} \ni z \longmapsto \mathcal{T}_{V}(z):=J|V|^{1 / 2}\left(H_{0}-z\right)^{-1}|V|^{1 / 2} \in S_{2}
$$

with $J:=\operatorname{sign} V$ defined so that $J^{2}=1$, has an analytic extension from $\mathcal{F}_{+}$ to $\mathcal{M}$, denoted again by $\mathcal{T}_{V}(z)$. Moreover the operator $\partial_{z} \mathcal{T}_{V}(z) \in S_{1}$ is analytic on $\mathcal{M}$. The vector field $\partial_{z}$ is defined as $\left(\pi_{G}^{-1}\right)_{*}\left(\partial_{\lambda}\right)$ where $\partial_{\lambda}$ is the canonical vector field on $\mathbb{C}$.

Proof. - The existence of the holomorphic extension in $S_{2}$ is a direct consequence of Proposition 1, because for any $N>0$, we have

$$
|V|^{1 / 2}=\mathcal{V}\left(v_{\perp} \otimes \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\right)
$$

with a bounded operator $\mathcal{V}$. In order to prove $\partial_{z} \mathcal{T}_{V}(z) \in S_{1}$, it suffices to check that the series of general term $\left(v_{\perp} p_{q} v_{\perp}\right) \otimes \partial_{z} t_{N}(z-2 b q)$ converge in the trace class. Arguing as in the proof of Proposition 1, we find that this convergence follows from (2.8), and the fact that for $z \in \mathbb{C} \backslash[0,+\infty[$, we have $\partial_{z} t_{N}(z)=\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(D_{x_{3}}^{2}-z\right)^{-2} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}$.

REMARK. - The assumption $m_{\perp}>2$ could be weakened to $m_{\perp}>1$ in the first part of the Lemma 1 while it is necessary for the second part.

Suppose (2.1) with $m_{\perp}>0$. Using

$$
(H-z)^{-1}\left(1+V\left(H_{0}-z\right)^{-1}\right)=\left(H_{0}-z\right)^{-1}
$$

we get

$$
\mathrm{e}^{-N\left\langle x_{3}\right\rangle}(H-z)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}=\mathrm{e}^{-N\left\langle x_{3}\right\rangle}\left(H_{0}-z\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}
$$

$$
\begin{equation*}
\times\left(1+\mathrm{e}^{N\left\langle x_{3}\right\rangle} V\left(H_{0}-z\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\right)^{-1} \tag{2.11}
\end{equation*}
$$

for $z \in \mathcal{F}_{+}, \operatorname{Im} z \gg 1$. From Proposition 1, combined with (2.1), the operator $V \mathrm{e}^{N\left\langle x_{3}\right\rangle}\left(H_{0}-z\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}$ is compact on $L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right)$. Then, the analytic Fredholm theorem implies the meromorphic extension of

$$
\left(1+\mathrm{e}^{N\left\langle x_{3}\right\rangle} V\left(H_{0}-z\right)^{-1} \mathrm{e}^{-N\left\langle x_{3}\right\rangle}\right)^{-1}
$$

from $\mathcal{F}_{+}$to $\mathcal{M}_{N}$. This now allows us to define the resonances of $H$.
Proposition 2. - Suppose $V$ satisfies (2.1) with $m_{\perp}>0$. Then the operator-valued function

$$
(H-z)^{-1}: \mathrm{e}^{-N\left\langle x_{3}\right\rangle} L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right) \longrightarrow \mathrm{e}^{N\left\langle x_{3}\right\rangle} L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right)
$$

has a meromorphic extension from the open upper half plane to $\mathcal{M}_{N}$. Moreover, the poles and the range of the residues of this extension do not depend on $N$.

Definition 3. - We define the resonances of $H$ as the poles of the meromorphic extension of the resolvent $(H-z)^{-1}$, denoted by $R(z)$. The multiplicity of a resonance $z_{0}$ is defined by

$$
\begin{equation*}
\operatorname{mult}\left(z_{0}\right):=\operatorname{rank} \frac{1}{2 i \pi} \int_{\gamma} R(z) \mathrm{d} z \tag{2.12}
\end{equation*}
$$

where $\gamma$ is a small positively oriented circle centered at $z_{0}$. Here, $\mathrm{d} z$ denotes the form $\pi_{G}^{*}(\mathrm{~d} \lambda)$ where $\mathrm{d} \lambda$ is the canonical 1 -form on $\mathbb{C}$.

In the sequel we will use also the regularized determinant $\operatorname{det}_{2}(I+A)$ defined for a Hilbert-Schmidt operator $A$ by

$$
\begin{equation*}
\operatorname{det}_{2}(I+A):=\operatorname{det}\left((I+A) \mathrm{e}^{-A}\right) \tag{2.13}
\end{equation*}
$$

Proposition 3. - Suppose $V$ satisfies (2.1) with $m_{\perp}>0$. The following assertions are equivalent:
(i) $z_{0} \in \mathcal{M}$ is a resonance of $H$;
(ii) $z_{0}$ is a pole of $|V|^{1 / 2} R(z)|V|^{1 / 2}$;
(iii) -1 is an eigenvalue of $\mathcal{T}_{V}\left(z_{0}\right)=J|V|^{1 / 2} R_{0}\left(z_{0}\right)|V|^{1 / 2}$.

Moreover, the rank of the residue of $|V|^{1 / 2} R(z)|V|^{1 / 2}$ at $z_{0}$ is equal to the multiplicity of the resonance of $H$.

Assume now that $V$ satisfies (2.1) with $m_{\perp}>2$. Then

$$
\begin{equation*}
\operatorname{det}_{2}\left((H-z)\left(H_{0}-z\right)^{-1}\right)=\operatorname{det}_{2}\left(I+\mathcal{T}_{V}(z)\right) \tag{2.14}
\end{equation*}
$$

has a analytic continuation from $\mathcal{F}_{+}$to $\mathcal{M}$. Its zeros are the resonances of $H$, and if $z_{0}$ is a resonance, there exists a holomorphic function $f(z)$, for $z$ close to $z_{0}$, such that $f\left(z_{0}\right) \neq 0$ and

$$
\begin{equation*}
\operatorname{det}_{2}\left(I+\mathcal{T}_{V}(z)\right)=\left(z-z_{0}\right)^{\ell\left(z_{0}\right)} f(z) \tag{2.15}
\end{equation*}
$$

with $0<\ell\left(z_{0}\right)=\operatorname{mult}\left(z_{0}\right)$ where mult $\left(z_{0}\right)$ is the multiplicity of the resonance defined by (2.12). The quantities $z-z_{0}$ and $H-z$ are defined as $\pi_{G}(z)-\pi_{G}\left(z_{0}\right)$ and $H-\pi_{G}(z)$ in (2.15) and in the following proof.

Remarks. - (i) The main part of the proof of Proposition 3 follows the arguments of [26]. To our best knowledge the novelty is the proof of (2.27) (i.e. the equality between the rank of the residue of $|V|^{1 / 2} R(z)|V|^{1 / 2}$ at $z_{0}$ and the multiplicity $\operatorname{mult}\left(z_{0}\right)$ ), and the equality $\ell\left(z_{0}\right)=\operatorname{mult}\left(z_{0}\right)$.
(ii) If $H$ and $H_{0}$ are two self-adjoint operators such that $H-H_{0} \in S_{1}$, the perturbation determinant $\operatorname{det}\left((H-\lambda)\left(H_{0}-\lambda\right)^{-1}\right), \operatorname{Im} \lambda>0$, was introduced by M.G. Krein in [19] (see also [16, Section IV.3]). In the case $H-H_{0} \in S_{r}$ with $r>1$ the generalized perturbation determinant

$$
\operatorname{det}_{r}\left((H-\lambda)\left(H_{0}-\lambda\right)^{-1}\right)
$$

was introduced in [17]. In the last work, relatively Hilbert-Schmidt perturbations and the corresponding generalized perturbation determinants $\operatorname{det}_{2}\left((H-\lambda)\left(H_{0}-\lambda\right)^{-1}\right)$ were considered as well; these determinants are exactly of the same type as the one appearing in (2.13).
(iii) For potentials $V$ compactly supported with respect to $x_{3}$, the resonances can be defined as the poles of the meromorphic extension of the resolvent:

$$
\begin{equation*}
(H-z)^{-1}: L_{\text {comp }}^{2}\left(\mathbb{R}_{x_{3}}, L^{2}\left(\mathbb{R}_{X_{\perp}}^{2}\right)\right) \longrightarrow L_{\mathrm{loc}}^{2}\left(\mathbb{R}_{x_{3}}, L^{2}\left(\mathbb{R}_{X_{\perp}}^{2}\right)\right) \tag{2.16}
\end{equation*}
$$

from the open upper half plane to $\mathcal{M}$ (see [26] for the Schrödinger operator $-\Delta+V)$.

Proof. - Clearly, if $z_{0}$ is a pole of $|V|^{1 / 2} R(z)|V|^{1 / 2}$ then it is a pole of $R(z)$ and conversely according to the resolvent equation

$$
\begin{align*}
R(z)= & R_{0}(z)-  \tag{2.17}\\
= & R(z) V R_{0}(z) \\
= & R_{0}(z)- \\
& R_{0}(z) V R_{0}(z) \\
& +R_{0}(z)|V|^{1 / 2} J|V|^{1 / 2} R(z)|V|^{1 / 2} J|V|^{1 / 2} R_{0}(z),
\end{align*}
$$

if $z_{0}$ is a pole of $R(z)$ then it is a pole of $|V|^{1 / 2} R(z)|V|^{1 / 2}$, and (i) is equivalent to (ii).

From the resolvent equation we get

$$
\begin{equation*}
\left(I+J|V|^{1 / 2} R_{0}(z)|V|^{1 / 2}\right)\left(I-J|V|^{1 / 2} R(z)|V|^{1 / 2}\right)=I \tag{2.18}
\end{equation*}
$$

From Proposition 2 and Lemma 1, we deduce that $z_{0}$ is a resonance if and only if -1 is an eigenvalue of $\mathcal{T}_{V}\left(z_{0}\right)$, and (ii) is equivalent to (iii).

Now we check the preservation of the multiplicity. Let $z_{0} \in \mathcal{M}$ be a resonance and $N>0$ be large enough to have $z_{0} \in \mathcal{M}_{N}$. For $z$ close to $z_{0}$, the resolvents, as operators from $L_{-N}^{2}:=\mathrm{e}^{-N\left\langle x_{3}\right\rangle} L^{2}\left(\mathbb{R}_{\mathbf{x}}^{3}\right)$ to $L_{N}^{2}$, can be written in the form

$$
\begin{align*}
R_{0}(z) & =\sum_{j \geqslant 0} M_{j}\left(z-z_{0}\right)^{j}  \tag{2.19}\\
R(z) & =\left(z-z_{0}\right)^{-L} A_{-L}+\cdots+\left(z-z_{0}\right)^{-1} A_{-1}+\operatorname{Hol}(z) \tag{2.20}
\end{align*}
$$

were the last term is holomorphic in a neighborhood of $z=z_{0}$. Classically, for $\gamma$ a small positively oriented circle centered at $z_{0}$, we have

$$
\begin{equation*}
A_{-j}=\frac{1}{2 i \pi} \int_{\gamma}\left(z-z_{0}\right)^{j-1} R(z) \mathrm{d} z, \quad j \geqslant 1, \tag{2.21}
\end{equation*}
$$

mult $\left(z_{0}\right)$ being the rank of $A_{-1}$, and

$$
\begin{equation*}
A_{-j}\left(H-z_{0}\right)=\left(H-z_{0}\right) A_{-j}=A_{-j-1} \tag{2.22}
\end{equation*}
$$

Our next goal is to check the identities

$$
\begin{align*}
& \operatorname{rank}\left(A_{-1}\right)=\operatorname{rank}\left(V A_{-1}\right),  \tag{2.23}\\
& \operatorname{rank}\left(A_{-1}^{*}\right)=\operatorname{rank}\left(V A_{-1}^{*}\right) \tag{2.24}
\end{align*}
$$

Let us prove (2.23). If this identity is false, there exists a function $f$ such that $f=A_{-1} g$ and $V f=0$. Since $f$ belongs to the range of $A_{-1}$, the distribution $H^{m} f$ is in $L_{\text {loc }}^{2}\left(\mathbb{R}^{3}\right)$, for any $m \in \mathbb{N}$. In particular, $H f=$ $H_{0} f \in H_{\mathrm{loc}}^{2}\left(\mathbb{R}^{3}\right)$, and hence $f \in H_{\mathrm{loc}}^{4}\left(\mathbb{R}^{3}\right) \subset C^{2}\left(\mathbb{R}^{3}\right)$.

Further, $V f=0$ easily implies $V H f=0$. By recurrence, we obtain

$$
\begin{equation*}
V H^{n} f=0 \tag{2.25}
\end{equation*}
$$

for any $n \in \mathbb{N}$. Plugging (2.20) into the r.h.s. of the resolvent equation

$$
R(z)=R_{0}(z)-R_{0}(z) V R(z)
$$

and integrating with respect to $z \in \gamma$, we find that (2.22) entails

$$
\begin{equation*}
f=A_{-1} g=-\sum_{j=0}^{L-1} M_{j} V A_{-j-1} g=-\sum_{j=0}^{L-1} M_{j} V\left(H-z_{0}\right)^{j} f \tag{2.26}
\end{equation*}
$$

Using (2.25) and (2.26), we get $f=0$ which immediately yields (2.23). Identity (2.24) can be proved exactly in the same way.

Applying (2.23)-(2.24), we get

$$
\operatorname{rank}\left(A_{-1}\right)=\operatorname{rank}\left(A_{-1} V\right)
$$

next

$$
\operatorname{rank}\left(A_{-1}\right)=\operatorname{rank}\left(A_{-1} V\right)=\operatorname{rank}\left(A_{-1}|V|^{1 / 2}\right)
$$

and, moreover, find that $|V|^{1 / 2}$ is injective on the range of $\left(A_{-1}\right)$. Thus we obtain

$$
\begin{equation*}
\operatorname{rank}\left(A_{-1}\right)=\operatorname{rank}\left(|V|^{1 / 2} A_{-1}|V|^{1 / 2}\right) \tag{2.27}
\end{equation*}
$$

which implies that the multiplicities agree.
We now prove the second part of the proposition. Let us recall that, if $A$ is a bounded operator and if $B$ is a trace class operator on some separable Hilbert space, we have $\operatorname{det}(I+A B)=\operatorname{det}(I+B A)$. Moreover, for $A$ bounded and $B$ Hilbert-Schmidt, we have

$$
\begin{equation*}
\operatorname{det}_{2}(I+A B)=\operatorname{det}_{2}(I+B A) \tag{2.28}
\end{equation*}
$$

Writing, for $z \in \mathcal{F}_{+}$,

$$
(H-z)\left(H_{0}-z\right)^{-1}=I+V\left(H_{0}-z\right)^{-1}
$$

where $J|V|^{1 / 2}\left(H_{0}-z\right)^{-1}$ is holomorphic on $\mathcal{F}_{+}$, with value in the HilbertSchmidt class, and using (2.28), we get

$$
\begin{aligned}
\operatorname{det}_{2}\left((H-z)\left(H_{0}-z\right)^{-1}\right) & =\operatorname{det}_{2}\left(I+|V|^{1 / 2} J|V|^{1 / 2}\left(H_{0}-z\right)^{-1}\right) \\
& =\operatorname{det}_{2}\left(I+\mathcal{T}_{V}(z)\right)
\end{aligned}
$$

From Lemma 1, this determinant has an analytic extension from $\mathcal{F}_{+}$to $\mathcal{M}$ and vanishes if and only if $z_{0}$ is a resonance of $H$. Then, there exists a holomorphic function $f(z)$, for $z$ close to $z_{0}$, such that $f\left(z_{0}\right) \neq 0$ and

$$
\operatorname{det}_{2}\left(I+\mathcal{T}_{V}(z)\right)=\left(z-z_{0}\right)^{\ell\left(z_{0}\right)} f(z)
$$

In order to prove that $\ell\left(z_{0}\right)=\operatorname{mult}\left(z_{0}\right)$ where $\operatorname{mult}\left(z_{0}\right)$ is the multiplicity of the resonance defined by (2.12), we need the following

Lemma 2. - The operator

$$
\Pi_{-1}=-A_{-1} \sum_{L-1 \geqslant j, k \geqslant 0}\left(H-z_{0}\right)^{j} V M_{j+k+1} V\left(H-z_{0}\right)^{k},
$$

is well defined in $\mathcal{L}\left(\mathcal{H}_{N}^{L-1}\right)$ for any $N$ where $\mathcal{H}_{N}^{L}$ is the Hilbert space

$$
\begin{aligned}
& \mathcal{H}_{N}^{L}:=\left\{u \in L_{N}^{2}\left(\mathbb{R}^{3}\right)=L^{2}\left(\mathbb{R}^{3}, \mathrm{e}^{-N\left|x_{3}\right|} \mathrm{d} x\right)\right. \\
&\text { such that } \left.H^{k} u \in L_{N}^{2}\left(\mathbb{R}^{3}\right), \text { for all } k \leqslant L\right\}
\end{aligned}
$$

equipped with the norm $\sum_{0 \leqslant k \leqslant L}\left\|H^{k} u\right\|_{L_{N}^{2}}$.
For any $k \in \mathbb{N}$, in $\mathcal{L}\left(L_{-N}^{2}, \mathcal{H}_{N}^{k}\right)$ we have

$$
\begin{equation*}
\Pi_{-1} A_{-1}=A_{-1} \tag{2.29}
\end{equation*}
$$

Here $\mathcal{L}(A, B)$ (resp. $\mathcal{L}(A))$ denotes the space of linear bounded operator from $A$ to $B$ (resp. $A$ ).

Proof of Lemma 2. - We recall that from (2.26),

$$
\begin{equation*}
A_{-1}=-\sum_{j \geqslant 0} M_{j} V A_{-j-1}, \tag{2.30}
\end{equation*}
$$

with the convention that $A_{-j}=0$ for $j>L$. On the other hand, the resolvent equation

$$
R_{0}(z)=R(z)\left(I+V R_{0}(z)\right)
$$

yields

$$
\begin{equation*}
M_{j}=\sum_{k \leqslant j} A_{k} \widetilde{M}_{j-k} \tag{2.31}
\end{equation*}
$$

with $\widetilde{M}_{0}=I+V M_{0}, \widetilde{M}_{j}=V M_{j}$ for $j \geqslant 1$, and the equation $R_{0}(z)=$ $\left(I+R_{0}(z) V\right) R(z)$ implies for any $k \geqslant 0$ :

$$
\begin{equation*}
0=\sum_{j \geqslant k} \widetilde{\widetilde{M}}_{j-k} A_{-j-1} \tag{2.32}
\end{equation*}
$$

with $\widetilde{\widetilde{M}}_{0}=I+M_{0} V, \widetilde{\widetilde{M}}_{j}=M_{j} V, \widetilde{\widetilde{M}}_{-j}=0$ for $j \geqslant 1$. In the above equality we use again the convention that $A_{-j}=0$ for $j>L$. By inserting (2.31) into (2.30), we deduce

$$
A_{-1}=-\sum_{j \geqslant 0} \sum_{k \leqslant j} A_{k} \widetilde{M}_{j-k} V A_{-j-1}
$$

Since $\widetilde{M}_{j} V=V \widetilde{\widetilde{M}}_{j}$ and $A_{-1}\left(H-z_{0}\right)^{j}=A_{-1-j}$, relation (2.32) implies

$$
A_{-1}=-\sum_{j \geqslant 0} \sum_{k<0} A_{k} V M_{j-k} V A_{-j-1}=\Pi_{-1} A_{-1}
$$

This concludes the proof of Lemma 2.
Let us now complete the proof of Proposition 3. It follows from Lemma 2 that $\operatorname{rank} \Pi_{-1}=\operatorname{rank} A_{-1}$ and (2.29) implies that $\Pi_{-1} \Pi_{-1}=\Pi_{-1}$. Consequently, we have

$$
\begin{equation*}
\operatorname{mult}\left(z_{0}\right)=\operatorname{rank} A_{-1}=\operatorname{tr} \Pi_{-1} \tag{2.33}
\end{equation*}
$$

On the other hand, by the definition of $\ell\left(z_{0}\right)$, we have

$$
\begin{equation*}
\ell\left(z_{0}\right)=\frac{1}{2 i \pi} \int_{\gamma} \partial_{z} \ln \operatorname{det}_{2}\left(1+\mathcal{T}_{V}(z)\right) \mathrm{d} z \tag{2.34}
\end{equation*}
$$

Further, we have

$$
\partial_{z} \ln \operatorname{det}(1+T(z))=\operatorname{tr}\left((1+T(z))^{-1} \partial_{z} T(z)\right), \quad z \in \Omega
$$

for any operator-valued holomorphic function $z \mapsto T(z) \in S_{1}$ defined on an open set $\Omega \subset \mathbb{C}$. Therefore,

$$
\partial_{z} \ln \operatorname{det}_{2}\left(1+\mathcal{T}_{V}(z)\right)=\operatorname{tr}\left(\left(1+\mathcal{T}_{V}(z)\right)^{-1} \partial_{z} \mathcal{T}_{V}(z)\right)-\operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(z)\right)
$$

According to Lemma $1, \partial_{z} \mathcal{T}_{V}(z)$ is holomorphic in the trace class, then its integral on $\gamma$ vanishes and (2.18) yields

$$
\ell\left(z_{0}\right)=-\frac{1}{2 i \pi} \int_{\gamma} \operatorname{tr}\left(J|V|^{1 / 2} R(z) V \partial_{z} R_{0}(z)|V|^{1 / 2}\right) \mathrm{d} z
$$

By definition of $A_{-k}$ and $M_{j}$, we obtain

$$
\ell\left(z_{0}\right)=-\operatorname{tr}\left(\sum_{L \geqslant k \geqslant 1} J|V|^{1 / 2} A_{-k} k V M_{k}|V|^{1 / 2}\right)
$$

where the trace is on $L^{2}$. We have $A_{-k}=A_{-1}\left(H-z_{0}\right)^{k-1}$ in $\mathcal{L}\left(L_{-N}^{2}, L_{N}^{2}\right)$, thanks to (2.22), and using the cyclicity of the trace,

$$
\begin{equation*}
\ell\left(z_{0}\right)=-\operatorname{tr}\left(\sum_{L \geqslant k \geqslant 1} A_{-1}\left(H-z_{0}\right)^{k-1} k V M_{k} V\right) . \tag{2.35}
\end{equation*}
$$

Here the trace is in $L_{N}^{2}$, but since the range of $A_{-1}$ is in any $\mathcal{H}_{N}^{j}, j \geqslant 1$, the last trace is also in any $\mathcal{H}_{N}^{j}$. At last, combining the cyclicity of the trace, with (2.22), (2.33) and (2.35) we deduce

$$
\operatorname{mult}\left(z_{0}\right)=\operatorname{tr}\left(\Pi_{-1}\right)=\operatorname{tr}\left(-\sum_{0 \leqslant j, k \leqslant L-1} A_{-1}\left(H-z_{0}\right)^{k+j} V M_{k+j+1} V\right)=\ell\left(z_{0}\right)
$$

## 3. Resonances near the Landau levels

In this section we assume that $V$ satisfies (2.1) with $m_{\perp}>2$, and study the resonances localized in $D_{q}^{*}$, the neighborhood of the Landau level $2 b q$ introduced in Definition 2. Recall that $D_{q}^{*}$ can be parametrized by $z_{q}(k)$ defined in (2.5).

According to the previous section, these resonances can be identified with the points $z$ where the determinant $\operatorname{det}_{2}\left(I+T_{V}(z)\right)$ vanishes. Note that $\mathcal{T}_{V}(z)$ is the holomorphic extension of

$$
\begin{align*}
& J|V|^{1 / 2}\left(H_{0}-z\right)^{-1}|V|^{1 / 2}  \tag{3.1}\\
&=\sum_{j \in \mathbb{N}} J|V|^{1 / 2} P_{j}\left(H_{0}-z\right)^{-1}|V|^{1 / 2}, \quad z \in \mathcal{F}_{+},
\end{align*}
$$

where $P_{j}=p_{j} \otimes I_{x_{3}}, j \in \mathbb{N}$.
In order to study the resonances near a Landau level $2 b q$ we split $\mathcal{T}_{V}(z)$ into two parts:

$$
\mathcal{T}_{V}(z)=J|V|^{1 / 2} P_{q} R_{0}(z)|V|^{1 / 2}+\sum_{j \neq q} J|V|^{1 / 2} P_{j} R_{0}(z)|V|^{1 / 2}
$$

By Proposition 1, the second term in the r.h.s. is holomorphic in a neighborhood of $2 b q$ with values in $S_{2}$. Let us consider the first term for $z=z_{q}(k)$. The series expansion with respect to $k$ of the kernel of the operator $t_{N}$ (see (2.3) and (2.4)) allows us to write $t_{N}$ as the sum

$$
\begin{equation*}
t_{N}\left(k^{2}\right)=\frac{1}{k} t_{1}+r_{1}(k), \tag{3.2}
\end{equation*}
$$

where $t_{1}: L^{2}(\mathbb{R}) \rightarrow L^{2}(\mathbb{R})$ is the rank-1 operator defined by

$$
\begin{equation*}
t_{1} u:=\frac{i}{2}\left\langle u, \mathrm{e}^{-N\langle\cdot\rangle}\right\rangle \mathrm{e}^{-N\left\langle x_{3}\right\rangle}, \tag{3.3}
\end{equation*}
$$

and $r_{1}(k)$ is the Hilbert-Schmidt operator with integral kernel

$$
\begin{equation*}
\mathcal{R}_{1}\left(x_{3}, x_{3}^{\prime}\right)=\mathrm{e}^{-N\left\langle x_{3}\right\rangle} i \frac{\mathrm{e}^{i k\left|x_{3}-x_{3}^{\prime}\right|}-1}{2 k} \mathrm{e}^{-N\left\langle x_{3}^{\prime}\right\rangle} . \tag{3.4}
\end{equation*}
$$

Clearly, the operator-valued function $\mathbb{C} \ni k \mapsto r_{1}(k) \in S_{2}$ is analytic. Putting together the above considerations, we obtain the following

Proposition 4. - Suppose $V$ satisfies (2.1) with $m_{\perp}>2$. For $k \in \mathbb{C}^{*}$, $|k|<\sqrt{2 b}$, we have

$$
\begin{equation*}
\mathcal{T}_{V}\left(z_{q}(k)\right)=\frac{i J}{k} B_{q}+A(k) \tag{3.5}
\end{equation*}
$$

where $J=\operatorname{sign} V, B_{q}$ is the positive self-adjoint operator

$$
\begin{equation*}
B_{q}=\frac{1}{2}|V|^{1 / 2} P_{q}|V|^{1 / 2} \tag{3.6}
\end{equation*}
$$

and $A(k) \in S_{2}$ is the holomorphic operator defined on the open disc $\{k \in \mathbb{C} ;|k|<\sqrt{2 b}\}$ by

$$
\begin{equation*}
A(k)=J A_{q}(k)+J \sum_{j \neq q}|V|^{1 / 2} P_{j} R_{0}\left(z_{q}(k)\right)|V|^{1 / 2} \tag{3.7}
\end{equation*}
$$

where $A_{q}(k)$ is the operator with integral kernel

$$
\begin{aligned}
\mathcal{K}_{A_{q}}\left(X_{\perp}, x_{3} ; X_{\perp}^{\prime}, x_{3}^{\prime}\right)=\mid V( & \left.X_{\perp}, x_{3}\right)\left.\right|^{1 / 2} \mathcal{P}_{q, b}\left(X_{\perp}, X_{\perp}^{\prime}\right) \\
& \times \frac{1-\mathrm{e}^{i k\left|x_{3}-x_{3}^{\prime}\right|}}{2 i k}\left|V\left(X_{\perp}^{\prime}, x_{3}^{\prime}\right)\right|^{1 / 2}
\end{aligned}
$$

Here, $\mathcal{P}_{q, b}$ is the integral kernel of the orthogonal projection $p_{q}$ written in (2.10).

Since there exists an operator $C: L^{2}\left(\mathbb{R}^{3}\right) \rightarrow L^{2}\left(\mathbb{R}^{2}\right)$ such that $B_{q}=C^{*} C$ and $C C^{*}=\frac{1}{2} p_{q} W p_{q}$ with

$$
\begin{equation*}
W\left(X_{\perp}\right)=\int_{\mathbb{R}}\left|V\left(X_{\perp}, x_{3}\right)\right| \mathrm{d} x_{3} \tag{3.8}
\end{equation*}
$$

(see [30] for $q=0$, and the proof of Proposition 5.3 of [11] for any $q \in \mathbb{N}$ ), then for any $s>0$ we have

$$
\begin{equation*}
n_{+}\left(s ; B_{q}\right)=n_{+}\left(2 s ; p_{q} W p_{q}\right) \tag{3.9}
\end{equation*}
$$

where for a compact self-adjoint operator $A$, we set

$$
n_{+}(s ; A)=\operatorname{rank} \mathbf{1}_{(s,+\infty)}(A)
$$

Remark. - Using (2.18) and (3.5), we can prove that each Landau level is an essential singularity of the resolvent of $H$, but it is not sufficient to deduce the existence of an infinite number of resonances near the Landau levels.

Let $U$ be a function in $L^{\infty}\left(\mathbb{R}^{2}\right)$. In the case where the decay of $U$ at infinity is regular enough, the asymptotic distribution of the eigenvalues of Toeplitz-type operators $p_{q} U p_{q}$ is well known. The following three lemmas describe the eigenvalue asymptotics for $p_{q} U p_{q}$ in the case of power-like decay, exponential decay, or compact support of $U$, respectively.

Lemma 3 (Theorem 2.6 of [22]). - Let the function $U \in C^{1}\left(\mathbb{R}^{2}\right)$ satisfy the estimates

$$
0 \leqslant U\left(X_{\perp}\right) \leqslant C_{1}\left\langle X_{\perp}\right\rangle^{-\alpha}, \quad\left|\nabla U\left(X_{\perp}\right)\right| \leqslant C_{1}\left\langle X_{\perp}\right\rangle^{-\alpha-1}, \quad X_{\perp} \in \mathbb{R}^{2}
$$

for some $\alpha>0$ and $C_{1}>0$. Assume, moreover that

$$
U\left(X_{\perp}\right)=u_{0}\left(X_{\perp} /\left|X_{\perp}\right|\right)\left|X_{\perp}\right|^{-\alpha}(1+o(1)), \quad\left|X_{\perp}\right| \rightarrow \infty
$$

where $u_{0}$ is a continuous function on $\mathbb{S}^{1}$ which is non-negative and does not vanish identically. Then for each $q \in \mathbb{N}$ we have

$$
n_{+}\left(s ; p_{q} U p_{q}\right)=C_{\alpha} s^{-2 / \alpha}(1+o(1)), \quad s \searrow 0
$$

where

$$
\begin{equation*}
C_{\alpha}:=\frac{b}{4 \pi} \int_{\mathbb{S}^{1}} u_{0}(t)^{2 / \alpha} \mathrm{d} t \tag{3.10}
\end{equation*}
$$

Lemma 4 (Theorem 2.1 of [25]). - Let $0 \leqslant U \in L^{\infty}\left(\mathbb{R}^{2}\right)$. Assume that

$$
\ln U\left(X_{\perp}\right)=-\mu\left|X_{\perp}\right|^{2 \beta}(1+o(1)), \quad\left|X_{\perp}\right| \rightarrow \infty
$$

for some $\beta>0, \mu>0$. Then for each $q \in \mathbb{N}$ we have

$$
n_{+}\left(s ; p_{q} U p_{q}\right)=\varphi_{\beta}(s)(1+o(1)), \quad s \searrow 0
$$

where for $0<s<\mathrm{e}^{-1}$ we have put

$$
\varphi_{\beta}(s):= \begin{cases}\frac{1}{2} b \mu^{-1 / \beta}|\ln s|^{1 / \beta} & \text { if } 0<\beta<1 \\ \frac{1}{\ln (1+2 \mu / b)}|\ln s| & \text { if } \beta=1 \\ \frac{\beta}{\beta-1}(\ln |\ln s|)^{-1}|\ln s| & \text { if } \beta>1\end{cases}
$$

Lemma 5 (Theorem 2.4 of [25]). - Let $0 \leqslant U \in L^{\infty}\left(\mathbb{R}^{2}\right)$. Assume that the support of $U$ is compact and there exists a constant $C>0$ such that $U \geqslant C$ on an non-empty open subset of $\mathbb{R}^{2}$. Then for each $q \in \mathbb{N}$ we have

$$
n_{+}\left(s ; p_{q} U p_{q}\right)=\varphi_{\infty}(s)(1+o(1)), \quad s \searrow 0
$$

where

$$
\varphi_{\infty}(s):=(\ln |\ln s|)^{-1}|\ln s|, \quad 0<s<\mathrm{e}^{-1}
$$

REMARK. - In the recent article [12] a sharper version of the result of Lemma 5 has been obtained, containing three asymptotic terms as $s \searrow 0$ of $n_{+}\left(s ; p_{q} U p_{q}\right)$ provided that the support of $U$ is compact, and $U$ satisfies some additional technical assumptions. In particular, the asymptotic expansion of $n_{+}\left(s ; p_{q} U p_{q}\right)$ obtained in [12] recovers the logarithmic capacity of the support of $U$.

The above lemmas imply some useful properties of $B_{q}$ summarized in the following

Corollary 1. - Let $s>0$. For $V$ satisfying (1.1) with $m_{\perp}>2$, the operator $B_{q}$ is a trace class operator with $n_{+}\left(s, B_{q}\right)=\mathcal{O}\left(s^{-2 / m_{\perp}}\right)$ for $s>0$ small enough. For $j \in \mathbb{N}^{*}:=\{1,2, \ldots\}$, the operator-valued functions

$$
\begin{equation*}
\mathbb{C} \backslash\left(\mp i \left[0,+\infty[) \ni k \longmapsto \mathcal{B}(k)=\mathcal{B}_{q, j}^{ \pm}(k):=\frac{i B_{q}}{k}\left(I \pm \frac{i B_{q}}{k}\right)^{-j} \in S_{1}\right.\right. \tag{3.11}
\end{equation*}
$$

are holomorphic. Their Hilbert-Schmidt norms $(p=2)$ and trace-class norms ( $p=1$ ) satisfy the estimates

$$
\begin{equation*}
\|\mathcal{B}(k)\|_{p} \leqslant c(\theta)^{j} \sigma_{p}(|k|)^{\frac{1}{p}}, \tag{3.12}
\end{equation*}
$$

where $\theta=\operatorname{Arg} k, c(\theta)=\left(1-(\sin \theta)_{-}\right)^{-\frac{1}{2}}, u_{-}:=\max \{-u, 0\}$ if $u \in \mathbb{R}$, and

$$
\begin{equation*}
\sigma_{p}(s):=\left\|\frac{B_{q}}{s}\left(I+\frac{B_{q}^{2}}{s^{2}}\right)^{-1 / 2}\right\|_{p}^{p}=\mathcal{O}\left(s^{-2 / m_{\perp}}\right), \quad s>0 \tag{3.13}
\end{equation*}
$$

Further, for $s>0, p \geqslant 1$, we have

$$
\begin{equation*}
2^{-p / 2} \widetilde{n}_{p}(s) \leqslant \sigma_{p}(s) \leqslant \widetilde{n}_{p}(s)+n_{+}\left(s, B_{q}\right) \tag{3.14}
\end{equation*}
$$

where

$$
\begin{equation*}
\widetilde{n}_{p}(s):=\left\|\frac{B_{q}}{s} \mathbf{1}_{[0, s]}\left(B_{q}\right)\right\|_{p}^{p}, \quad s>0, p \geqslant 1 . \tag{3.15}
\end{equation*}
$$

Moreover, for $W$ defined by (3.8) satisfying the assumptions of Lemma 3 with $\alpha>2$, the estimates

$$
\left\{\begin{array}{l}
\sigma_{p}(s)=C_{\alpha, p} s^{-2 / \alpha}(1+o(1)),  \tag{3.16}\\
\widetilde{n}_{p}(s)=\widetilde{C}_{\alpha, p} s^{-2 / \alpha}(1+o(1)),
\end{array} \quad s \searrow 0\right.
$$

hold with some $C_{\alpha, p}>0, \widetilde{C}_{\alpha, p}>0, p=1,2$. Finally, if the assumptions of Lemma 4 or of Lemma 5 hold for $W=U$, we have

$$
\begin{equation*}
\sigma_{p}(s)=\varphi_{\beta}(s)(1+o(1)), \quad \tilde{n}_{p}(s)=o\left(\varphi_{\beta}(s)\right), \quad s \searrow 0 \tag{3.17}
\end{equation*}
$$

the functions $\varphi_{\beta}(s), 0<\beta \leqslant \infty$, being defined in Lemma 4 or in Lemma 5.

Proof. - By (3.9), $B_{q} \in S_{1}$ if and only if $p_{q} W p_{q} \in S_{1}$. For $V$ satisfying (1.1), we have $0 \leqslant W\left(X_{\perp}\right) \leqslant C\left\langle X_{\perp}\right\rangle^{-m_{\perp}}$. Therefore, $W \in L^{1}\left(\mathbb{R}^{2}\right)$, and hence $p_{q} W p_{q} \in S_{1}$, and then $B_{q} \in S_{1}$. According to Lemma 3, $n_{+}\left(s ; p_{q} C\left\langle X_{\perp}\right\rangle^{-m_{\perp}} p_{q}\right)$ behaves like $s^{-2 / m_{\perp}}$ as $s \searrow 0$, then $n_{+}\left(s ; B_{q}\right)=$ $\mathcal{O}\left(s^{-2 / m_{\perp}}\right)$ for $s>0$ small enough. Taking also into account that $B_{q} \geqslant 0$, we conclude that the operator-valued functions $\mathcal{B}$ defined in (3.11) are holomorphic. Let us now estimate their norms in $S_{1}$ and in $S_{2}$. For $k=|k| \mathrm{e}^{i \theta}$, we have

$$
\mathcal{B}^{*} \mathcal{B}=\frac{B_{q}^{2}}{|k|^{2}}\left(I+\frac{B_{q}^{2}}{|k|^{2}} \pm 2 \sin \theta \frac{B_{q}}{|k|}\right)^{-j}
$$

Next,

$$
\begin{align*}
\|\mathcal{B}\|_{S_{p}}^{p} & =-\int_{0}^{\infty} f_{j, p}\left(\frac{u}{|k|}, \pm \theta\right) \mathrm{d} n_{+}\left(u ; B_{q}\right)  \tag{3.18}\\
& =-\int_{0}^{\infty} f_{j, p}(s, \pm \theta) \mathrm{d} n_{+}\left(s ; \frac{B_{q}}{|k|}\right)
\end{align*}
$$

where $f_{j, p}(u, \theta):=u^{p}\left(1+u^{2}+2 u \sin \theta\right)^{-j p / 2}$. Evidently, for $\theta \neq-\frac{1}{2} \pi$ and $u \geqslant 0$ we have

$$
\begin{equation*}
f_{j, p}(u, \theta) \leqslant c(\theta)^{j p} f_{p}(u) \tag{3.19}
\end{equation*}
$$

where $f_{p}(u):=u^{p}\left(1+u^{2}\right)^{-p / 2}, p=1,2$. Finally,

$$
\begin{equation*}
\sigma_{p}(s)=\operatorname{tr}\left(\frac{B_{q}^{p}}{s^{p}}\left(I+\frac{B_{q}^{2}}{s^{2}}\right)^{-p / 2}\right)=-\int_{0}^{\infty} f_{p}(u) \mathrm{d} n_{+}\left(u ; \frac{B_{q}}{s}\right) \tag{3.20}
\end{equation*}
$$

Now the combination of (3.18), (3.19), and (3.20), yields (3.12). We have also

$$
\begin{equation*}
\widetilde{n}_{p}(s)=-\int_{0}^{1} u^{p} \mathrm{~d} n_{+}\left(u ; \frac{B_{q}}{s}\right) \tag{3.21}
\end{equation*}
$$

Then (3.14) is a consequence of the elementary inequalities

$$
2^{-p / 2} u^{p} \mathbf{1}_{[0,1]}(u) \leqslant f_{p}(u) \leqslant u^{p} \mathbf{1}_{[0,1]}(u)+\mathbf{1}_{] 1,+\infty[ }(u)
$$

In order to prove (3.16)-(3.17), since $\lim _{u \downarrow 0} u n_{+}\left(u ; B_{q}\right)=0$, we first note that relations (3.20), (3.21) and (3.9) imply

$$
\begin{align*}
& \sigma_{p}(s)=\int_{0}^{\infty} f_{p}^{\prime}(u) n_{+}\left(2 s u ; p_{q} W p_{q}\right) \mathrm{d} u  \tag{3.22}\\
& \widetilde{n}_{p}(s)=\int_{0}^{1} p u^{p-1}\left(n_{+}\left(2 s u ; p_{q} W p_{q}\right)-n_{+}\left(2 s ; p_{q} W p_{q}\right)\right) \mathrm{d} u \tag{3.23}
\end{align*}
$$

Then for $W$ satisfying the assumptions of Lemma 3 or of Lemma 4 or of Lemma 5 we deduce the asymptotic properties claimed.

Proposition 5. - Suppose that $V$ satisfies (2.1) with $m_{\perp}>2$. For $0<s<|k|<s_{0}$ with $s_{0}$ sufficiently small, $z_{q}(k) \in D_{q}^{*}$ is a resonance of $H$ if and only if $k$ is a zero of

$$
\begin{equation*}
D(k, s)=\operatorname{det}(I+K(k, s)) \tag{3.24}
\end{equation*}
$$

where $K(k, s)$ is a finite-rank operator analytic with respect to $k$, and satisfying

$$
\operatorname{rank} K(k, s)=\mathcal{O}\left(n_{+}\left(s ; p_{q} W p_{q}\right)+1\right), \quad\|K(k, s)\|=\mathcal{O}\left(s^{-1}\right)
$$

uniformly with respect to $s<|k|<s_{0}$.
Moreover, for $\operatorname{Im} k^{2}>\delta>0$, the operator $I+K(k, s)$ is invertible with

$$
\left\|(I+K(k, s))^{-1}\right\|=\mathcal{O}\left(\delta^{-1}\right)
$$

uniformly with respect to $s<|k|<s_{0}, \operatorname{Im} k^{2}>\delta$.
Proof. - By Propositions 3-4, for $s<|k| \leqslant s_{0}<\sqrt{2 b}, z_{q}(k)$ is a resonance of $H$ if and only if $k$ is a zero of $\operatorname{det}_{2}\left(I+(i J / k) B_{q}+A(k)\right)$.

Since $k \mapsto A(k)$ is holomorphic near $k=0$ with value in $S_{2}$, for $s_{0}$ sufficiently small, there exist a finite-rank operator $A_{0}$ independent of $k$ and $\widetilde{A}(k)$ holomorphic near $k=0$ in $S_{2}$ with $\|\widetilde{A}(k)\| \leqslant \frac{1}{4},|k| \leqslant s_{0}$ such that

$$
A(k)=A_{0}+\widetilde{A}(k)
$$

Further, let us decompose the self-adjoint positive operator $B_{q}$ into a trace-class operator whose norm is bounded by $\frac{1}{2} s$, and an operator of rank $n_{+}\left(\frac{1}{2} s ; B_{q}\right)$, namely

$$
\begin{equation*}
B_{q}=B_{q} \mathbf{1}_{\left[0, \frac{1}{2} s\right]}\left(B_{q}\right)+B_{q} \mathbf{1}_{] \frac{1}{2} s,+\infty[ }\left(B_{q}\right) \tag{3.25}
\end{equation*}
$$

Since $\left\|(i J / k) B_{q} \mathbf{1}_{\left[0, \frac{1}{2} s\right]}\left(B_{q}\right)+\widetilde{A}(k)\right\| \leqslant \frac{3}{4}$, for $0<s<|k|<s_{0}$, we have

$$
\operatorname{det}\left(\left(I+\frac{i J}{k} B_{q} \mathbf{1}_{\left[0, \frac{1}{2} s\right]}\left(B_{q}\right)+\widetilde{A}(k)\right) \mathrm{e}^{-\mathcal{T}_{V}\left(z_{q}(k)\right)}\right) \neq 0
$$

It follows that for $0<s<|k|<s_{0}$, the zeros of $\operatorname{det}_{2}\left(I+\mathcal{T}_{V}\left(z_{q}(k)\right)\right)$ are the zeros of $D(k, s)$ defined by (3.24) with

$$
K(k, s)=\left(\frac{i J}{k} B_{q} \mathbf{1}_{] \frac{1}{2} s,+\infty[ }\left(B_{q}\right)+A_{0}\right)\left(I+\frac{i J}{k} B_{q} \mathbf{1}_{\left[0, \frac{1}{2} s\right]}\left(B_{q}\right)+\widetilde{A}(k)\right)^{-1}
$$

The rank of this operator is bounded by

$$
\mathcal{O}\left(n_{+}\left(\frac{1}{2} s ; B_{q}\right)+1\right)=\mathcal{O}\left(n_{+}\left(s ; p_{q} W p_{q}\right)+1\right)
$$

(see (3.9)) and its norm is bounded by $\mathcal{O}\left(|k|^{-1}\right)$.

At last, by the definition of $\mathcal{T}_{V}(z)$ and of $K(k, s)$, we have

$$
I+K(k, s)=\left(I+\mathcal{T}_{V}\left(z_{q}(k)\right)\right)\left(I+\frac{i J}{k} B_{q} \mathbf{1}_{\left[0, \frac{1}{2} s\right]}\left(B_{q}\right)+\widetilde{A}(k)\right)^{-1}
$$

provided that $0<s<|k|<s_{0}$. By the resolvent equation (2.18), the operator $I+\mathcal{T}_{V}(z)$ is invertible for $\operatorname{Im} z>\delta$, and

$$
\left(I+\mathcal{T}_{V}(z)\right)^{-1}=I-J|V|^{1 / 2}(H-z)^{-1}|V|^{1 / 2}
$$

Then $I+K(k, s)$ is invertible for $\operatorname{Im} k^{2}>\delta, 0<s<|k|<s_{0}$, and $\left\|(I+K(k, s))^{-1}\right\|=\mathcal{O}\left(1+\left\||V|^{1 / 2}\left(H-z_{q}(k)\right)^{-1}|V|^{1 / 2}\right\|\right)=\mathcal{O}\left(1+\left|\operatorname{Im} k^{2}\right|^{-1}\right)$ which concludes the proof of Proposition 5.

By the properties of $K(k, s)$ (see Proposition 5) for $0<s<|k|<s_{0}$, we have:

$$
\begin{align*}
D(k, s) & =\prod_{j=1}^{\mathcal{O}\left(n_{+}\left(s ; p_{q} W p_{q}\right)+1\right)}\left(1+\lambda_{j}(k, s)\right)  \tag{3.26}\\
& =\mathcal{O}(1) \exp \left(\mathcal{O}\left(n_{+}\left(s ; p_{q} W p_{q}\right)+1\right)|\ln s|\right)
\end{align*}
$$

uniformly with respect to $(k, s)$, where $\lambda_{j}(k, s)$ are the eigenvalues of $K(k, s)$ which satisfy $\lambda_{j}(k, s)=\mathcal{O}\left(|s|^{-1}\right)$.

Moreover, since

$$
D(k, s)^{-1}=\operatorname{det}\left((I+K)^{-1}\right)=\operatorname{det}\left(I-K(I+K)^{-1}\right),
$$

for $\operatorname{Im} k^{2}>\delta>0$, and for $0<s<|k|<s_{0}$, we have

$$
\begin{equation*}
|D(k, s)| \geqslant C \exp \left(-C\left(n_{+}\left(s ; p_{q} W p_{q}\right)+1\right)(|\ln \delta|+|\ln s|)\right) \tag{3.27}
\end{equation*}
$$

uniformly with respect to $(k, s)$.
The following lemma contains a version of the well-known Jensen inequality which is suitable for our purposes.

Lemma 6. - Let $\Omega$ be a simply connected sub-domain of $\mathbb{C}$ and let $g$ be a holomorphic function in $\Omega$ with continuous extension to $\bar{\Omega}$. Assume there exists $\lambda_{0} \in \Omega$ such that $g\left(\lambda_{0}\right) \neq 0$ and $g(\lambda) \neq 0$ for $\lambda \in \partial \Omega$. Let $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{N} \in \Omega$ be the zeros of $g$ repeated according to their multiplicity. For any domain $\Omega^{\prime} \subset \subset \Omega$, there exists $C^{\prime}>0$ such that $N\left(\Omega^{\prime}, g\right)$, the number of zeros $\lambda_{j}$ of $g$ contained in $\Omega^{\prime}$, satisfies

$$
N\left(\Omega^{\prime}, g\right) \leqslant C\left(\int_{\partial \Omega} \ln |g(\lambda)| \mathrm{d} \lambda-\ln \left|g\left(\lambda_{0}\right)\right|\right)
$$

Proof. - First, let us recall the classical Jensen inequality

$$
N(B(0, \nu R), G)|\ln \nu| \leqslant \frac{1}{2 \pi} \int_{0}^{2 \pi} \ln \left|G\left(R \mathrm{e}^{i \theta}\right)\right| \mathrm{d} \theta-\ln |G(0)|
$$

valid for any $0<\nu<1$, and for a function $g=G$ satisfying the assumptions of the lemma in $\Omega=B(0, R):=\{\lambda \in \mathbb{C} ;|\lambda|<R\}$, and $\lambda_{0}=0$.

Now, let $f: B(0, R) \rightarrow \Omega$ be a bijective analytic function such that $f(0)=\lambda_{0}$ and $f(\partial B(0, R))=\partial \Omega$. Then $G=g \circ f$ satisfies the assumptions of the lemma in $\Omega=B(0, R)$, with $\lambda_{0}=0$, and we have the above formula. Since $f$ is a bijection and $f(\partial B(0, R))=\partial \Omega$, for $\Omega^{\prime} \subset \subset \Omega$ there exists $0<\nu<1$ such that $\Omega^{\prime} \subset f(B(0, \nu R))$, which implies the claim of the lemma.

Applying this lemma to the function $g(k):=D(r k, r)$, on the subdomain $\Omega:=\left\{k \in \mathbb{C} ; 1<|k|<2, \frac{1}{3} \pi<\operatorname{Arg} k<2 \pi+\frac{1}{6} \pi\right\}$ with $\operatorname{Im} k_{0}^{2}>\delta>0$, we deduce from (3.26), (3.27) the following upper bound on the number of resonances near the Landau levels.

Theorem 1 (Upper bound). - Suppose that $V$ satisfies (2.1) with $m_{\perp}>2$. Then there exists $r_{0}>0$, such that for any $0<r<r_{0}$,

$$
\#\left\{z=z_{q}(k) \in \operatorname{Res}(H) \cap D_{q}^{*} ; r<|k|<2 r\right\}=\mathcal{O}\left(n_{+}\left(r, p_{q} W p_{q}\right)|\ln r|\right)
$$

where $W$ is given by (3.8), and $n_{+}\left(s ; p_{q} W p_{q}\right)$ is the counting function satisfying the asymptotic relations depending on the decay of $W$, described in Lemmas 3, 4 and 5. In particular, under our assumptions we have always $n_{+}\left(s ; p_{q} W p_{q}\right)=\mathcal{O}\left(s^{-2 / m_{\perp}}\right)$, and for $V$ compactly supported, we have $n_{+}\left(s ; p_{q} W p_{q}\right)=\mathcal{O}\left((\ln |\ln s|)^{-1}|\ln s|\right)$.

REmARK. - Instead of the 3-dimensional case considered in the present paper, it is possible to consider a general n-dimensional Schrödinger operator with non vanishing constant magnetic field $B$ which can be regarded as a real antisymmetric matrix acting in $\mathbb{R}^{n}$. Set $2 d=\operatorname{rank} B$ and $\widetilde{d}:=n-2 d$, so that in the 3 -dimensional case we have $d=1$ and $\widetilde{d}=1$. Note that the spectrum of the unperturbed Schrödinger operator $H_{0}(B)$ with magnetic field $B$ is pure point if $\widetilde{d}=0$, and is purely absolutely continuous if $\widetilde{d} \geqslant 1$. For $\tilde{d} \geqslant 1$ the unperturbed operator can be written in appropriate Cartesian coordinates $(x, y, z) \in \mathbb{R}^{n}$ with $x, y \in \mathbb{R}^{d}$ and $z \in \mathbb{R}^{\widetilde{d}}$, as

$$
\sum_{j=1}^{d}\left(\left(D_{x_{j}}+\frac{1}{2} b_{j} y_{j}\right)^{2}+\left(D_{y_{j}}-\frac{1}{2} b_{j} x_{j}\right)^{2}\right)+\sum_{l=1}^{\widetilde{d}} D_{z_{\ell}}^{2}
$$

where $B=\sum_{j=1}^{d} b_{j} \mathrm{~d} x_{j} \wedge \mathrm{~d} y_{j}$. We believe that the presence of infinitely many resonances is typical for the cases $\widetilde{d}=1$ and $\widetilde{d}=2$. However, the

Riemann surfaces where the resonances are defined, and the eigenvalue counting functions for the corresponding Toeplitz operators (see [22]) which occur in the estimates of the resonances, should be of different type in these two cases. On the other hand, if $\widetilde{d} \geqslant 3$, we expect that the number of the resonances near any fixed Landau level should be finite. The qualitative pictures in the cases $\widetilde{d}=1, \widetilde{d}=2$, and $\widetilde{d} \geqslant 3$, should be independent of the rank $2 d$ of the non-vanishing magnetic field $B$.

## 4. Perturbations of definite sign

In this section, we discuss the case $\pm V \geqslant 0$. We will obtain an upper bound of the number of resonances near the Landau levels outside a semiaxis. Further, for small perturbations, we prove the existence of a region free of resonances, and obtain a lower bound on the number of resonances near a semi-axis. In particular, we show that for small non-negative perturbations there are no embedded eigenvalues.

In the definite-sign case, we can summarize our results by Figure 2.
Let $V$ have a definite sign, i.e. let $J=\operatorname{sign} V$ be constant, $J= \pm 1$ when $\pm V \geqslant 0$. In this case, according to Proposition 4, we have

$$
\mathcal{T}_{V}\left(z_{q}(k)\right)=\frac{i}{k} J B_{q}+A(k)
$$

with $B_{q}$ a positive self-adjoint operator independent of $k$, and $A(k)$ holomorphic near $k=0$ with values in $S_{2}$. For $i J k \notin \operatorname{sp}\left(B_{q}\right)$, the operator $I+(i / k) J B_{q}$ is invertible with

$$
\left\|\left(I+\frac{i}{k} J B_{q}\right)^{-1}\right\| \leqslant \frac{|k|}{\sqrt{(J \operatorname{Im} k)_{+}^{2}+|\operatorname{Re} k|^{2}}}
$$

and for $-\delta J \operatorname{Im} k<|\operatorname{Re} k|$, the estimate $\left\|\left(I+(i / k) J B_{q}\right)^{-1}\right\| \leqslant \sqrt{1+\delta^{-2}}$ holds uniformly with respect to $k,|k|<s_{0},-\delta J \operatorname{Im} k<|\operatorname{Re} k|$.

We have

$$
I+\mathcal{T}_{V}\left(z_{q}(k)\right)=(I+K(k))\left(I+\frac{i}{k} J B_{q}\right)
$$

with

$$
K(k):=A(k)\left(I+\frac{i}{k} J B_{q}\right)^{-1} .
$$

Figure 4.1. Resonances near a Landau level for $V$ of definite sign. Resonances $z=z_{q}(k)$ are concentrated near the semi axis $k=$ $-i(\operatorname{sign} V)] 0,+\infty[$. Moreover, for any $\theta$, the number of resonances in $C_{\theta}$ is bounded by $\mathcal{O}(|\ln r|)$ for $s_{0}=s_{0}(\theta)$ sufficiently small (Proposition 6). On the other hand, for any $0<s_{0}<\sqrt{2 b}$ and any $\theta$, there is no resonance of $H_{0}+\varepsilon V$ in $C_{\theta}$ for $\varepsilon \leqslant \varepsilon_{0}(\theta)$ sufficiently small, and for compactly supported $V$ we have a lower bound of the number of resonances in $S_{\theta}$ (see Theorem 2).

Note that $K(k) \in S_{2}$, and its Hilbert-Schmidt norm is uniformly bounded with respect to $k$, for $|k|<s_{0},-\delta J \operatorname{Im} k<|\operatorname{Re} k|$. Therefore,

$$
\begin{align*}
& \operatorname{det}_{2}\left(I+\mathcal{T}_{V}\left(z_{q}(k)\right)\right)=\operatorname{det}\left(I+\frac{i}{k} J B_{q}\right)  \tag{4.1}\\
& \times \operatorname{det}(I+K(k)) \mathrm{e}^{-\operatorname{Tr}\left(\mathcal{T}_{V}\left(z_{q}(k)\right)-K(k)\right)}
\end{align*}
$$

This relation is obtained by approximating the Hilbert-Schmidt operator $K$ by a finite-rank operator, and using the fact that for a trace-class operator $B$, we have $\operatorname{det}_{2}(I+B)=\operatorname{det}(I+B) \mathrm{e}^{-\operatorname{tr} B}$. We exploit moreover, the fact that since $B_{q}$ is a trace class operator (see Corollary 1), then such is $\left(\mathcal{T}_{V}\left(z_{q}(k)\right)-K(k)\right)=(I+K(k))(i / k) J B_{q}$.

According to (4.1), for $|k|<s_{0},-\delta J \operatorname{Im} k<|\operatorname{Re} k|$, the zeros of

$$
\operatorname{det}_{2}\left(I+\mathcal{T}_{V}\left(z_{q}(k)\right)\right)
$$

are the zeros of $\operatorname{det}_{2}(I+K(k))$. By the properties of $K(k)$,

$$
\operatorname{det}_{2}(I+K(k))=\mathcal{O}\left(\mathrm{e}^{C\|K(k)\|_{2}^{2}}\right)=\mathcal{O}(1)
$$

uniformly with respect to $k$. On the other hand, writing

$$
(I+K)^{-1}=\left(I+\frac{i}{k} J B_{q}\right)\left(I+\mathcal{T}_{V}\right)^{-1}
$$

and arguing as in the proof of Proposition 5, we find that

$$
\left\|(I+K)^{-1}\right\|=\mathcal{O}\left(|s|^{-1}\right) \mathcal{O}\left(\delta^{-1}\right)
$$

for $\operatorname{Im} k^{2}>\delta>0$, and for $0<s<|k|<s_{0}$, uniformly with respect to $(k, s)$. If $\left(\lambda_{j}\right)_{j}$ denotes the sequence of eigenvalues of $K(k)$, the above estimate implies that for $\operatorname{Im} k^{2}>\delta>0$, and for $0<s<|k|<s_{0}$, we have

$$
\begin{equation*}
\left|1+\lambda_{j}\right|^{-1}=\mathcal{O}\left(|s|^{-1}\right) \mathcal{O}\left(\delta^{-1}\right) \tag{4.2}
\end{equation*}
$$

Now, we are able to establish a lower bound of $\operatorname{det}_{2}(I+K(k))$. We have

$$
\begin{aligned}
\left|\left(\operatorname{det}_{2}(I+K(k))\right)^{-1}\right| & =\left|\operatorname{det}\left((I+K(k))^{-1} \mathrm{e}^{K(k)}\right)\right| \\
& \leqslant \prod_{\left|\lambda_{j}\right| \leqslant \frac{1}{2}}\left|\frac{\mathrm{e}^{\lambda_{j}}}{1+\lambda_{j}}\right| \times \prod_{\left|\lambda_{j}\right|>\frac{1}{2}} \frac{\mathrm{e}^{\left|\lambda_{j}\right|}}{\left|1+\lambda_{j}\right|}
\end{aligned}
$$

The first product is uniformly bounded because $K(k)$ is uniformly bounded in $S_{2}$ and we estimate the second product by $\mathcal{O}\left(e^{C(|\ln \delta|+|\ln s|)}\right)$ using the fact that it involves a finite number of factors bounded by $\mathcal{O}\left(|s|^{-1}\right) \mathcal{O}\left(\delta^{-1}\right)$ (see (4.2)). We get

$$
\left|\operatorname{det}_{2}(I+K(k))\right| \geqslant C \mathrm{e}^{-C(|\ln \delta|+|\ln s|)}
$$

for $\operatorname{Im} k^{2}>\delta>0$, and for $0<s<|k|<s_{0}$. Consequently, from the Jensen inequality (Lemma 6), in the case $V$ of definite sign, we establish upper bounds outside a neighborhood of $\left\{z_{q}(k) ; k \in(-i J)[0,+\infty[ \}\right.$ :

Proposition 6 (Upper bound: special case). - Suppose that $V$ satisfying (2.1) with $m_{\perp}>2$, is of definite sign $J$. For any $\delta>0$, there exists $s_{0}>0$, such that for any $0<r<s_{0}$ we have
$\#\left\{z=z_{q}(k) \in \operatorname{Res}(H) \cap D_{q}^{*} ; r<|k|<2 r,-\delta J \operatorname{Im} k<|\operatorname{Re} k|\right\}=\mathcal{O}(|\ln r|)$.
In what follows, we prove also that for small perturbations of definite sign the resonances are near $z_{q}(k), k$ being an eigenvalues of $-i J B_{q}$. In particular, we have a infinite number of resonances close to the Landau levels.

In order to obtain our lower bound of the counting function of resonances, we need the following result deduced from Lemma 4.

Lemma 7. - Let $0 \leqslant W \in L^{\infty}\left(\mathbb{R}^{2}\right)$ such that

$$
\begin{equation*}
\ln W\left(X_{\perp}\right) \leqslant-C\left\langle X_{\perp}\right\rangle^{2} \tag{4.3}
\end{equation*}
$$

for some $C>0$. Let $\left(\lambda_{j}\right)_{j}$ be the non-increasing sequence of the nonvanishing eigenvalues of $p_{q} W p_{q}$, counted with their multiplicity. Then there
exists $\nu>0$ such that

$$
\begin{equation*}
\#\left\{j ; \lambda_{j}-\lambda_{j+1}>\nu \lambda_{j}\right\}=\infty \tag{4.4}
\end{equation*}
$$

Proof. - By assumption, one can find a function $U$ which satisfies the hypotheses of Lemma 4 with $\beta=1$ such that $W \leqslant U$. Then we have $p_{q} W p_{q} \leqslant p_{q} U p_{q}$ and

$$
\begin{equation*}
n_{+}\left(s ; p_{q} W p_{q}\right) \leqslant n_{+}\left(s ; p_{q} U p_{q}\right)=\mathcal{O}(|\ln s|) \tag{4.5}
\end{equation*}
$$

by the min-max principle.
Let us assume that the set $\left\{j ; \lambda_{j}-\lambda_{j+1}>\nu \lambda_{j}\right\}$ is finite for any $\nu>0$. Then there exists $j_{\nu}$ such that for any $j \geqslant j_{\nu}, \lambda_{j}-\lambda_{j+1} \leqslant \nu \lambda_{j}$. This implies that for any $j>j_{\nu}, \lambda_{j} \geqslant(1-\nu)^{j-j_{\nu}} \lambda_{j_{\nu}}$. In this case for $s$ sufficiently small we would have

$$
n_{+}\left(s ; p_{q} W p_{q}\right)=\#\left\{j ; \lambda_{j}>s\right\} \geqslant \#\left\{j ;(1-\nu)^{j-j_{\nu}} \lambda_{j_{\nu}}>s\right\}
$$

that is

$$
n_{+}\left(s ; p_{q} W p_{q}\right) \geqslant|\ln (1-\nu)|^{-1} \cdot|\ln s|-\mathcal{O}_{\nu}(1)
$$

If we choose $\nu>0$ small enough, this lower bound is in contradiction with the estimate (4.5).

Theorem 2 (Sector free of resonances, upper and lower bound). - Let $0<s_{0}<\sqrt{2 b}$ and $q \in \mathbb{N}$. Assume that $V$ satisfies (2.1) with $m_{\perp}>2$ and is of definite sign $J$. Then for any $\delta>0$ there exists $\varepsilon_{0}>0$ such that:
(i) For any $\varepsilon \leqslant \varepsilon_{0}, H_{\varepsilon}:=H_{0}+\varepsilon V$ has no resonances in

$$
\left\{z=z_{q}(k) \in D_{q}^{*} ; 0<|k|<s_{0},-J \operatorname{Im} k \leqslant \frac{1}{\delta}|\operatorname{Re} k|\right\}
$$

(ii) There exists $r_{0}>0$, such that for any $0<r<r_{0}$ and $\varepsilon \leqslant \varepsilon_{0}$, we have

$$
\begin{align*}
\#\left\{z=z_{q}(k)\right. & \left.\in \operatorname{Res}\left(H_{\varepsilon}\right) \cap D_{q}^{*} ; r<|k|<2 r\right\}  \tag{4.6}\\
& =\mathcal{O}\left(n_{+}\left(r, \varepsilon p_{q} W p_{q}\right)-n_{+}\left(8 r, \varepsilon p_{q} W p_{q}\right)\right)
\end{align*}
$$

(iii) If $W$ defined by (3.8) satisfies (4.3), then for any $\varepsilon \leqslant \varepsilon_{0}, H_{\varepsilon}$ has an infinite number of resonances in

$$
\left\{z=z_{q}(k) \in D_{q}^{*} ; 0<|k|<s_{0},-J \operatorname{Im} k>\frac{1}{\delta}|\operatorname{Re} k|\right\} .
$$

More precisely, there exists a decreasing sequence $\left(r_{\ell}\right)_{\ell \in \mathbb{N}}$ of positive numbers, $r_{\ell} \searrow 0$ such that,

$$
\begin{gather*}
\#\left\{z=z_{q}(k) \in \operatorname{Res}\left(H_{\varepsilon}\right) \cap D_{q}^{*} ; r_{\ell+1}<|k|<r_{\ell},-J \operatorname{Im} k>\frac{1}{\delta}|\operatorname{Re} k|\right\} \\
\geqslant \operatorname{rank} \mathbf{1}_{\left[2 r_{\ell+1}, 2 r_{\ell}\right]}\left(\varepsilon p_{q} W p_{q}\right) \tag{4.7}
\end{gather*}
$$

Proof. - (i) We have

$$
\begin{equation*}
I+\mathcal{T}_{\varepsilon V}=I+\varepsilon \mathcal{T}_{V}=I+\frac{i}{k} \varepsilon J B_{q}+\varepsilon A(k) \tag{4.8}
\end{equation*}
$$

Since $B_{q}$ is self-adjoint and positive, the operator $I+(i / k) \varepsilon J B_{q}$ is invertible for $-J \operatorname{Im} k<(1 / \delta)|\operatorname{Re} k|$, and we have

$$
\left\|\left(I+\frac{i}{k} \varepsilon J B_{q}\right)^{-1}\right\| \leqslant \sqrt{1+\delta^{-2}} .
$$

Moreover, for $|k| \leqslant s_{0}$ there exists $C>0$ such that $\|A(k)\| \leqslant C$. Consequently, for $\varepsilon<\left(C \sqrt{1+\delta^{-2}}\right)^{-1}$ and $-J \operatorname{Im} k \leqslant(1 / \delta)|\operatorname{Re} k|$, the operator $I+(i / k) \varepsilon J B_{q}+\varepsilon A(k)$ is invertible and $z_{q}(k)$ is not a resonance of $H_{0}+\varepsilon V$.
(ii) We prove this point like Theorem 1. Let

$$
B^{+}:=\varepsilon B_{q} \mathbf{1}_{] r / 2,4 r[ }\left(\varepsilon B_{q}\right) \quad \text { and } \quad B^{-}:=\varepsilon B_{q} \mathbf{1}_{[0, r / 2] \cup[4 r,+\infty[ }\left(\varepsilon B_{q}\right) .
$$

For $\frac{2}{3} r<|k|<\frac{3}{2} r$, the spectrum of the self-adjoint operator $(1 /|k|) B^{-}$is a subset of $\left[0, \frac{3}{4}\right] \cup\left[\frac{8}{3},+\infty\left[\right.\right.$. Then $I+(i / k) J B^{-}$is invertible and

$$
\left\|\left(I+\frac{i}{k} J B^{-}\right)^{-1}\right\| \leqslant 4
$$

So, if $\varepsilon_{0}$ is small enough and $0 \leqslant \varepsilon \leqslant \varepsilon_{0}$, the operator $I+(i / k) J B^{-}+\varepsilon A(k)$ is invertible for $\frac{2}{3} r<|k|<\frac{3}{2} r$ with a uniformly bounded inverse.

Using (4.8), we can write

$$
\begin{align*}
I+\mathcal{T}_{\varepsilon V} & =I+\frac{i}{k} J B^{+}+\frac{i}{k} J B^{-}+\varepsilon A(k) \\
4.9) & =\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)\left(I+\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)^{-1} \frac{i}{k} J B^{+}\right), \tag{4.9}
\end{align*}
$$

and, from Proposition 3, the resonances of $H_{\varepsilon}$, with $\frac{2}{3} r<|k|<\frac{3}{2} r$, are the zeros of

$$
\begin{equation*}
\widetilde{D}(k, r):=\operatorname{det}\left(I+\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)^{-1} \frac{i}{k} J B^{+}\right) . \tag{4.10}
\end{equation*}
$$

Moreover, the multiplicity of the resonance, $\operatorname{mult}\left(z_{q}(k)\right)$, is equal to the order of the zero of $\widetilde{D}(k, r)$. Since $B^{+} / k$ is uniformly bounded, there exists $C>0$ such that

$$
\begin{equation*}
|\widetilde{D}(k, r)| \leqslant \exp \left(C \operatorname{rank} \mathbf{1}_{] r / 2,4 r[ }\left(\varepsilon B_{q}\right)\right) \tag{4.11}
\end{equation*}
$$

On the other hand, we have

$$
\begin{align*}
\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)^{-1} \frac{i}{k} J B^{+} & =\left(I+\left(I+\frac{i}{k} J B^{-}\right)^{-1} \varepsilon A(k)\right)^{-1} \frac{i}{k} J B^{+} \\
& =\frac{i}{k} J B^{+}+\mathcal{O}(\varepsilon) . \tag{4.12}
\end{align*}
$$

For $u \in L^{2}\left(\mathbb{R}^{3}\right), \frac{2}{3} r<|k|<\frac{3}{2} r$ and $k \in \mathbb{R}$, we get

$$
\begin{align*}
& \operatorname{Re}\left\langle\left(I+\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)^{-1} \frac{i}{k} J B^{+}\right) u, u\right\rangle  \tag{4.13}\\
& =\operatorname{Re}\left\langle\left(I+\frac{i}{k} J B^{+}+\mathcal{O}(\varepsilon)\right) u, u\right\rangle \\
& =\operatorname{Re}\langle(I+\mathcal{O}(\varepsilon)) u, u\rangle \geqslant \frac{1}{2}\|u\|^{2}
\end{align*}
$$

for $\varepsilon>0$ small enough. Since we can obtain the same estimate for the adjoint, the operator $I+\left(I+(i / k) J B^{-}+\varepsilon A(k)\right)^{-1}(i / k) J B^{+}$is invertible for $\frac{2}{3} r<|k|<\frac{3}{2} r, k \in \mathbb{R}$ with a uniformly bounded inverse. Then, for such $k$, we get

$$
\begin{aligned}
(\widetilde{D}(k, r))^{-1}= & \operatorname{det}\left(I-\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)^{-1}\right. \\
& \left.\times \frac{i}{k} J B^{+}\left(I+\left(I+\frac{i}{k} J B^{-}+\varepsilon A(k)\right)^{-1} \frac{i}{k} J B^{+}\right)^{-1}\right) \\
\leqslant & \exp \left(C \operatorname{rank} \mathbf{1}_{] r / 2,4 r[ }\left(\varepsilon B_{q}\right)\right)
\end{aligned}
$$

Combining this estimate with (4.11), the Jensen inequality and (3.9), we get (4.6).
(iii) According to Lemma 7, there exists $\nu>0$ and a decreasing sequence $\left(r_{\ell}\right)_{\ell \in \mathbb{N}}$ of positive numbers, $r_{\ell} \searrow 0$ such that for any $\ell \in \mathbb{N}$ we have

$$
\operatorname{dist}\left(r_{\ell}, \operatorname{sp}\left(B_{q}\right)\right) \geqslant \frac{1}{2} \nu r_{\ell} .
$$

Then for any $\ell \in \mathbb{N}$, there exists a path (see Figure 3)

$$
\widetilde{\Gamma}_{\ell} \subset\left\{\widetilde{k} \in \mathbb{C}^{*} ;|\widetilde{k}| \leqslant s_{0},|\operatorname{Im} \widetilde{k}| \geqslant \delta \operatorname{Re} \widetilde{k}, r_{\ell} \geqslant \operatorname{Re} \widetilde{k} \geqslant r_{\ell+1}\right\}
$$

enclosing the eigenvalues of $B_{q}$ contained in the interval $\left[r_{\ell+1}, r_{\ell}\right]$, and such that for $\widetilde{k} \in \widetilde{\Gamma}_{\ell}$, the operator $\widetilde{k}-B_{q}$ is invertible with

$$
\left\|\left(\widetilde{k}-B_{q}\right)^{-1}\right\|=\sup _{\lambda_{j} \in \operatorname{sp}\left(B_{q}\right)} \frac{1}{\left|\widetilde{k}-\lambda_{j}\right|} \leqslant \frac{C}{|\widetilde{k}|}
$$

for some $C=C(\delta, \nu)$, uniformly with respect to $\widetilde{k} \in \widetilde{\Gamma}_{\ell}$.
Now, let us consider the path $\Gamma_{\ell}:=i \varepsilon J \widetilde{\Gamma_{\ell}}$, and estimate from below the number of the zeros of $\operatorname{det}_{2}\left(I+(i / k) \varepsilon J B_{q}+\varepsilon A(k)\right)$ counted with their multiplicity, enclosed in $\left\{z=z_{q}(k) \in D_{q}^{*} ; k \in \Gamma_{\ell}\right\}$.

By construction of $\widetilde{\Gamma_{\ell}}$, for $k \in \Gamma_{\ell}$, the operator $I+i k^{-1} \varepsilon J B_{q}$ is invertible with $\left\|\left(I+i k^{-1} \varepsilon J B_{q}\right)^{-1}\right\| \leqslant C(\delta, \nu)$ uniformly with respect to $k \in \Gamma_{\ell}$. Then choosing $\varepsilon_{0}$ so small that

$$
\left\|\varepsilon_{0} A(k)\left(I+i k^{-1} \varepsilon J B_{q}\right)^{-1}\right\|_{2}<\frac{1}{2},
$$

Figure 4.2. The path $\widetilde{\Gamma}_{\ell}$
and using that $\operatorname{det}_{2}(I+A) \leqslant \mathrm{e}^{\|A\|_{2} / 2}$, we obtain that for $k \in \Gamma_{\ell}$,

$$
\left|\operatorname{det}_{2}\left(I+\varepsilon_{0} A(k)\left(I+i k^{-1} \varepsilon J B_{q}\right)^{-1}\right)-1\right|<1
$$

Applying the Rouché Theorem we deduce that the number of zeros of $\operatorname{det}_{2}\left(I+(i / k) \varepsilon J B_{q}+\varepsilon A(k)\right)$ enclosed in $\left\{z=z_{q}(k) \in D_{q}^{*} ; k \in \Gamma_{\ell}\right\}$ is equal to the number of zeros of $\operatorname{det}_{2}\left(I+(i / k) \varepsilon J B_{q}\right)$ and using (3.9) it is given by $n_{+}\left(2 r_{\ell+1} ; p_{q} W p_{q}\right)-n_{+}\left(2 r_{\ell} ; p_{q} W p_{q}\right)$. Since each zero of $\operatorname{det}_{2}\left(I+(i / k) \varepsilon J B_{q}+\right.$ $\varepsilon A(k))$ is a resonance, with the same multiplicity, we deduce (4.7), and since the sequence $\left(r_{\ell}\right)_{\ell}$ is infinite, we conclude that the number of the resonances is infinite.

Since the embedded eigenvalues in $\mathbb{R} \backslash 2 b \mathbb{N}$ are resonances $z_{q}(k)$ with $\left.k \in \mathrm{e}^{i\{0, \pi / 2\}}\right] 0, \sqrt{2 b}[$, a simple consequence of the previous theorem is the absence of embedded eigenvalues in $] 2 b q-s_{0}^{2}, 2 b q[\cup] 2 b q, 2 b q+s_{0}^{2}$ [ for small non-negative $V$ and in $] 2 b q, 2 b q+s_{0}^{2}[$ for small non-positive $V$. In fact, by more precise estimates with respect to $q$, for small non-negative $V$, we prove absence of embedded eigenvalues in $\mathbb{R}^{+} \backslash 2 b \mathbb{N}$ and for small non-positive $V$, we obtain information about the localization of the embedded eigenvalues on the left of the Landau levels.

Proposition 7 (Absence of embedded eigenvalues). - Assume that $V$ satisfies (1.1) with $m_{\perp}>0$ and $m_{3}>2$. For a non-negative potential $V$, there exists $\varepsilon_{0}>0$ such that for any $\varepsilon \leqslant \varepsilon_{0}, H_{\varepsilon}:=H_{0}+\varepsilon V$ has no embedded eigenvalues in $\mathbb{R}^{+} \backslash 2 b \mathbb{N}$. For a non-positive potential $V$, there exists $\varepsilon_{0}>0$ and $C>0$ such that for any $\varepsilon \leqslant \varepsilon_{0}, H_{\varepsilon}:=H_{0}+\varepsilon V$ has no embedded eigenvalues in $\mathbb{R}^{+} \backslash(2 b \mathbb{N}+]-\varepsilon C, 0[)$.

Proof. - According to Proposition 2.6 of [7], for $V$ satisfying (1.1) with $m_{\perp}>0$ and $m_{3}>1$ there exists $C>0$ such that $H_{\varepsilon}$ has no embedded eigenvalues in $\mathbb{R}^{+} \backslash(2 b \mathbb{N}+]-\varepsilon C, \varepsilon C[)$. Then, following the proof of Theorem 2 (i) (or see proof of Proposition 2.5 of [7]), we have only to check that $\varepsilon_{0}>0$ can be chosen independently of $\lambda \in \mathbb{R}^{+} \backslash 2 b \mathbb{N}$ such that for any $\varepsilon \leqslant \varepsilon_{0}$ and $\lambda \in \mathbb{R}^{+} \backslash 2 b \mathbb{N}, I+\varepsilon \mathcal{T}_{V}(\lambda)$ is invertible when $V$ is non-negative. For negative $V$, we have to choose $\varepsilon_{0}>0$ such that for any $\varepsilon \leqslant \varepsilon_{0}$ and $\lambda \in \mathbb{R}^{+} \backslash(2 b \mathbb{N}+]-b, 0[), I+\varepsilon \mathcal{T}_{V}(\lambda)$ is invertible.

Let $\lambda \in \mathbb{R}^{+} \backslash 2 b \mathbb{N}$, then there exists $q \in \mathbb{N}$ and $k \in \mathbb{C},|k| \leqslant \sqrt{b}$ such that $\left.\lambda=2 b q+k^{2}(k \in] 0, \sqrt{b}\right]$ or $\left.\left.\left.k \in i\right] 0, \sqrt{b}\right]\right)$. We have

$$
\begin{aligned}
\mathcal{T}_{V}(\lambda) & =J|V|^{1 / 2} R_{0}(\lambda)|V|^{1 / 2} \\
& =J|V|^{1 / 2}\left\langle x_{3}\right\rangle^{m_{3} / 2}\left(\sum_{j \in \mathbb{N}} p_{j} \otimes t_{m_{3}}(\lambda-2 b j)\right)\left\langle x_{3}\right\rangle^{m_{3} / 2}|V|^{1 / 2}
\end{aligned}
$$

where $t_{m_{3}}$ is the continuous extension of $z \mapsto\left\langle x_{3}\right\rangle^{-m_{3} / 2}\left(D_{x_{3}}^{2}-z\right)^{-1}\left\langle x_{3}\right\rangle^{-m_{3} / 2}$ from $\operatorname{Im} z>0$ to $z \in \mathbb{R} \backslash\{0\}$. For $\mu \in \mathbb{R} \backslash\{0\}$, the integral kernel of $t_{m_{3}}(\mu)$ is given by

$$
\left\langle x_{3}\right\rangle^{-m_{3} / 2} i \frac{\mathrm{e}^{i k\left|x_{3}-x_{3}^{\prime}\right|}}{2 k}\left\langle x_{3}^{\prime}\right\rangle^{-m_{3} / 2}
$$

where $k=\sqrt{\mu}$ if $\mu>0$ and $k=i \sqrt{-\mu}$ if $\mu<0$.
It is clear that $\left\|t_{m_{3}}(\mu)\right\| \leqslant|\mu|^{-1}$ for $\mu<0$ and that $\left\|t_{m_{3}}(\mu)\right\| \leqslant$ $C\left(m_{3}\right)|\mu|^{-1 / 2}$ for $\mu>0$, with $C\left(m_{3}\right)=\frac{1}{2} \int\left\langle x_{3}\right\rangle^{-m_{3}} \mathrm{~d} x_{3}$ (for more details, see [7]).

From the above estimates, we immediately get:

$$
\left\|\sum_{j \neq q} p_{j} \otimes t_{m_{3}}(\lambda-2 b j)\right\| \leqslant \sup _{j \neq q}\left\|t_{m_{3}}(\lambda-2 b j)\right\| \leqslant \max \left(b^{-1}, C\left(m_{3}\right) b^{-\frac{1}{2}}\right)
$$

Moreover, the series expansion with respect to $k$ of the kernel of the operator $t_{m_{3}}$ allows us to write $p_{q} \otimes t_{m_{3}}(\lambda-2 b q)$ as the sum

$$
p_{q} \otimes t_{m_{3}}(\lambda-2 b q)=\frac{i}{k} p_{q} \otimes \tau+p_{q} \otimes \rho(k)
$$

where $\tau: L^{2}(\mathbb{R}) \rightarrow L^{2}(\mathbb{R})$ is the rank-1 operator defined by

$$
\tau u:=\frac{1}{2}\left\langle u,\langle.\rangle^{-m_{3} / 2}\right\rangle\left\langle x_{3}\right\rangle^{-m_{3} / 2},
$$

and $\rho(k)$ is the Hilbert-Schmidt operator with integral kernel

$$
\left\langle x_{3}\right\rangle^{-m_{3} / 2} i \frac{\mathrm{e}^{i k\left|x_{3}-x_{3}^{\prime}\right|}-1}{2 k}\left\langle x_{3}^{\prime}\right\rangle^{-m_{3} / 2}
$$

Since this integral kernel is bounded by $\mathcal{O}\left(\left\langle x_{3}\right\rangle^{-m_{3} / 2}\left|x_{3}-x_{3}^{\prime}\right|\left\langle x_{3}^{\prime}\right\rangle^{-m_{3} / 2}\right)$, uniformly with respect to $k,|k| \leqslant \sqrt{b}$, it follows that $p_{q} \otimes \rho(k)$ is uniformly bounded independently of $q$ and $\lambda$, for $m_{3}>2$.

Consequently, for $B:=|V|^{1 / 2}\left\langle x_{3}\right\rangle^{m_{3} / 2}\left(p_{q} \otimes \tau\right)\left\langle x_{3}\right\rangle^{m_{3} / 2}|V|^{1 / 2}$, we have

$$
\left\|\mathcal{T}_{V}(\lambda)-\frac{i J}{k} B\right\| \leqslant M
$$

with $M$ independent of $\lambda$. At last, for $J k \in \mathbb{R}$ or $J k \in i \mathbb{R}^{+}$, since $B$ is a positive self-adjoint operator, $\left\|\left(I+i \varepsilon J k^{-1} B\right)^{-1}\right\| \leqslant 1$. Then taking $\varepsilon_{0}<M^{-1}$, for $\varepsilon \leqslant \varepsilon_{0}, I+\varepsilon \mathcal{T}_{V}(\lambda)$ is invertible for any $\lambda \in \mathbb{R}^{+} \backslash 2 b \mathbb{N}$ when $J=1$ (i.e. $V \geqslant 0$ ) and for any $\lambda \in \mathbb{R}^{+} \backslash(2 b \mathbb{N}+]-b, 0[)$ when $J=-1$ (i.e. $V \leqslant 0$ ). This concludes the proof of Proposition 7.

Remark. - Further information concerning the localization of the eigenvalues of the operator $H$ for non-sign-definite potentials $V$ is contained in [7, Proposition 2.6].

## 5. Spectral shift function and resonances

In this section we represent the derivative of the spectral shift function (SSF) near the Landau levels as a sum of a harmonic measure related to resonances, and the imaginary part of a holomorphic function. As in [21], [6], [10], such representation justifies the Breit-Wigner approximation and implies a trace formula. We deduce also an asymptotic expansion of the SSF near a given Landau level; in the case of non-negative potentials $V$ which decay slowly enough as $\left|X_{\perp}\right| \rightarrow \infty$ this expansion yields a remainder estimate for the corresponding asymptotic relations obtained in [11].
In the case of a relative trace class perturbation, the SSF is related to the perturbation determinant by the Krein formula

$$
\begin{equation*}
\xi(\lambda)=\frac{1}{\pi} \lim _{\varepsilon \rightarrow 0^{+}} \operatorname{Arg} \operatorname{det}\left((H-\lambda-i \varepsilon)\left(H_{0}-\lambda-i \varepsilon\right)^{-1}\right) \tag{5.1}
\end{equation*}
$$

In our case, $|V|^{1 / 2}\left(H_{0}+i\right)^{-1}$ is in the Hilbert-Schmidt class, and the distribution

$$
\begin{equation*}
\xi^{\prime}: f \in C_{0}^{\infty}(\mathbb{R}) \longmapsto-\operatorname{tr}\left(f(H)-f\left(H_{0}\right)\right) \tag{5.2}
\end{equation*}
$$

is still well defined, but not the above perturbation determinant. Since $V\left(H_{0}+i\right)^{-2}$ is of trace class, we could give a meaning to (5.1) using meromorphic extension of the regularized Zeta function (see [5]), but it will be more convenient to introduce the regularized spectral shift function

$$
\begin{equation*}
\xi_{2}(\lambda)=\frac{1}{\pi} \lim _{\varepsilon \rightarrow 0^{+}} \operatorname{Arg} \operatorname{det}_{2}\left((H-\lambda-i \varepsilon)\left(H_{0}-\lambda-i \varepsilon\right)^{-1}\right) \tag{5.3}
\end{equation*}
$$

(see (2.13) for the definition of $\operatorname{det}_{2}$ ) whose derivative is the following distribution

$$
\begin{equation*}
\xi_{2}^{\prime}: f \in C_{0}^{\infty}(\mathbb{R}) \longmapsto-\operatorname{tr}\left(f(H)-f\left(H_{0}\right)-\left.\frac{\mathrm{d}}{\mathrm{~d} \varepsilon} f\left(H_{0}+\varepsilon V\right)\right|_{\varepsilon=0}\right) \tag{5.4}
\end{equation*}
$$

(see [17] or [5]). Let us note that in [5], these quantities are defined with the opposite sign. We will deduce the properties of the SSF from those of the regularized SSF by using the following lemma which is well known for perturbation of the Laplacian (see [18], [4]).

Lemma 8. - Let $V$ satisfies (2.1) with $m_{\perp}>2$. On $\mathbb{R} \backslash 2 b \mathbb{N}$, we have

$$
\begin{equation*}
\xi^{\prime}=\xi_{2}^{\prime}+\frac{1}{\pi} \operatorname{Im} \operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(.)\right) \tag{5.5}
\end{equation*}
$$

$\mathcal{T}_{V}(z)$ being defined in Lemma 1.
Proof. - According to Lemma $1, \operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}\right)$ is analytic on $\overline{\mathcal{F}}_{+}$. Then, exploiting (5.2) and (5.4), we have only to prove

$$
\begin{equation*}
\operatorname{tr}\left(\left.\frac{\mathrm{d}}{\mathrm{~d} \varepsilon} f\left(H_{0}+\varepsilon V\right)\right|_{\varepsilon=0}\right)=-\frac{1}{\pi} \int_{\mathbb{R}} f(\lambda) \operatorname{Im} \operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(\lambda)\right) \mathrm{d} \lambda \tag{5.6}
\end{equation*}
$$

for any $f \in C_{0}^{\infty}(\mathbb{R} \backslash 2 b \mathbb{N}$ ). By the Helffer-Sjöstrand formula (see [9] for instance), for $\tilde{f} \in C_{0}^{\infty}\left(\mathbb{R}^{2}\right)$ an almost analytic extension of $f$, (i.e., $\tilde{f}_{\mid \mathbb{R}}=f$ and $\left.\bar{\partial}_{\lambda} \widetilde{f}(\lambda)=\mathcal{O}\left(|\operatorname{Im} \lambda|^{\infty}\right)\right)$, we have

$$
\begin{equation*}
f\left(H_{0}+\varepsilon V\right)=-\frac{1}{\pi} \int_{\mathbb{C}} \bar{\partial} \widetilde{f}(z)\left(z-H_{0}-\varepsilon V\right)^{-1} L(\mathrm{~d} z) \tag{5.7}
\end{equation*}
$$

where $L(\mathrm{~d} z)$ denotes the Lebesgue measure on $\mathbb{C}$. This quantity is differentiable with respect to $\varepsilon$ and its derivative at $\varepsilon=0$ is given by

$$
\left.\frac{\mathrm{d}}{\mathrm{~d} \varepsilon} f\left(H_{0}+\varepsilon V\right)\right|_{\varepsilon=0}=-\frac{1}{\pi} \int_{\mathbb{C}} \bar{\partial} \widetilde{f}(z)\left(z-H_{0}\right)^{-1} V\left(z-H_{0}\right)^{-1} L(\mathrm{~d} z)
$$

Following the proof of Lemma 1, we check easily that for $\pm \operatorname{Im} z>0$ the operator $\left(z-H_{0}\right)^{-1} V\left(z-H_{0}\right)^{-1}$ is of trace class with trace norm bounded by $\mathcal{O}\left(|\operatorname{Im} z|^{-2}\right)$ and by cyclicity of the trace, for $\operatorname{Im} z>0$ we have
$\operatorname{tr}\left(\left(z-H_{0}\right)^{-1} V\left(z-H_{0}\right)^{-1}\right)=\operatorname{tr}\left(J|V|^{1 / 2}\left(z-H_{0}\right)^{-2}|V|^{1 / 2}\right)=-\operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(z)\right)$
and for $\operatorname{Im} z<0$

$$
\operatorname{tr}\left(\left(z-H_{0}\right)^{-1} V\left(z-H_{0}\right)^{-1}\right)=-\overline{\operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(\bar{z})\right)}
$$

Hence, $\left.\frac{\mathrm{d}}{\mathrm{d} \varepsilon} f\left(H_{0}+\varepsilon V\right)\right|_{\varepsilon=0}$ is of trace class, and

$$
\begin{aligned}
& \operatorname{tr}\left(\left.\frac{\mathrm{d}}{\mathrm{~d} \varepsilon} f\left(H_{0}+\varepsilon V\right)\right|_{\varepsilon=0}\right)=\frac{1}{\pi} \int_{\operatorname{Im} z>0} \bar{\partial} \widetilde{f}(z) \operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(z)\right) L(\mathrm{~d} z) \\
& \quad+\frac{1}{\pi} \int_{\operatorname{Im} z<0} \bar{\partial} \widetilde{f}(z) \overline{\operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(\bar{z})\right)} L(\mathrm{~d} z)
\end{aligned}
$$

Then the Green formula yields (5.6).
Let $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$be open relatively compact subsets of $\left.\pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b[$ with $\varepsilon_{0}>0,2 \theta_{0}+\varepsilon_{0}<2 \pi$. We assume that these sets are independent of $r$ and that $\mathcal{W}_{ \pm}$is simply connected. Also assume that the intersections between $\Omega_{ \pm}, \mathcal{W}_{ \pm}$and $\left.\pm\right] 0,2 b\left[\right.$ are intervals. Set $\left.I_{ \pm}=\mathcal{W}_{ \pm} \cap \pm\right] 0,2 b[$ and choose $0<s_{1}<\sqrt{\operatorname{dist}\left(0, \Omega_{ \pm}\right)}$. In the following, we will identify $2 b q+r \bullet$ with $\pi_{G}^{-1}(2 b q+r \bullet) \cap D_{q}^{*}$, for $\bullet=\mathcal{W}_{ \pm}, \Omega_{ \pm}, I_{ \pm}$.

Proposition 8. - Let $V$ satisfies (2.1) with $m_{\perp}>2$. For $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$ and $I_{ \pm}$as above, there exist functions $g_{ \pm}$holomorphic in $\Omega_{ \pm}$, such that for $\mu \in 2 b q+r I_{ \pm}$, we have

$$
\begin{align*}
\xi_{2}^{\prime}(\mu)=\frac{1}{r \pi} & \operatorname{Im} g_{ \pm}^{\prime}\left(\frac{\mu-2 b q}{r}, r\right)  \tag{5.8}\\
+ & \sum_{w \in \operatorname{Res}(H) \cap 2 b q+r \Omega_{ \pm}}^{\operatorname{Im} w \neq 0}< \\
& \frac{\operatorname{Im} w}{\pi|\mu-w|^{2}} \\
& \sum_{w \in \operatorname{Res}(H) \cap 2 b q+r I_{ \pm}} \delta(\mu-w) \\
& \quad-\frac{1}{\pi} \operatorname{Im} \operatorname{tr}\left(\partial_{z} \mathcal{T}_{V}(\mu)\right)
\end{align*}
$$

where $g_{ \pm}(z, r)$ satisfies the estimate

$$
\begin{align*}
& g_{ \pm}(z, r)=\mathcal{O}\left(n_{+}\left(s_{1} \sqrt{r} ; p_{q} W p_{q}\right)|\ln r|+\widetilde{n}_{1}\left(\frac{1}{2} s_{1} \sqrt{r}\right)+\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right)\right) \\
& \quad=\mathcal{O}\left(|\ln r| r^{-1 / m_{\perp}}\right) \tag{5.9}
\end{align*}
$$

uniformly with respect to $0<r<r_{0}$ and $z \in \mathcal{W}_{ \pm}$, with $\widetilde{n}_{p}, p=1,2$, defined by (3.23) or (3.15).

In order to obtain such a representation formula, the first step is the factorization of the generalized perturbation determinant. To this end, we need some complex-analysis results due to J. Sjöstrand, summarized in the following

Proposition 9 (see [28], [29]). - Let $\Omega \subset \mathbb{C}$ be a simply connected domain such that $\Omega \cap\{z \in \mathbb{C} ; \operatorname{Im} z>0\} \neq \emptyset$. Let $z \mapsto F(z, h), 0<h<h_{0}$,
be a family of holomorphic functions in $\Omega$, having at most a finite number $N(h) \in \mathbb{N}^{*}$ of zeros in $\Omega$. Assume that

$$
F(z, h)=\mathcal{O}(1) \mathrm{e}^{\mathcal{O}(1) N(h)}, \quad z \in \Omega
$$

and that there exist $C, \delta>0$, with $\Omega_{\delta}:=\Omega \cap\{z \in \mathbb{C} ; \operatorname{Im} z>\delta\} \neq \emptyset$, such that

$$
|F(z, h)| \geqslant \mathrm{e}^{-C N(h)}, \quad z \in \Omega_{\delta}
$$

Then for any $\widetilde{\Omega} \subset \subset \Omega$, there exists $g(., h)$ holomorphic in $\Omega$ such that

$$
F(z, h)=\prod_{j=1}^{N(h)}\left(z-z_{j}\right) \mathrm{e}^{g(z, h)}, \quad \frac{\mathrm{d}}{\mathrm{~d} z} g(z, h)=\mathcal{O}(N(h)), \quad z \in \widetilde{\Omega}
$$

where the $z_{j}$ are the zeros of $F(z, h)$ in $\Omega$.
Proof of Proposition 8. - Fix $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$, and consider the functions

$$
F_{ \pm}: z \in \Omega_{ \pm} \longmapsto D\left(\sqrt{r} \sqrt{z}, \sqrt{r} s_{1}\right)
$$

where

$$
\sqrt{z}= \begin{cases}\sqrt{\rho} \mathrm{e}^{i \theta / 2} & \text { for } z=\rho \mathrm{e}^{i \theta} \in \Omega_{+},  \tag{5.10}\\ i \sqrt{\rho} \mathrm{e}^{-i \theta / 2} & \text { for } z=-\rho \mathrm{e}^{-i \theta} \in \Omega_{-},\end{cases}
$$

and $D(k, s)$ is defined by (3.24). The functions $F_{ \pm}$are holomorphic in $\Omega_{ \pm}$ and $\widetilde{w} \in \Omega_{ \pm}$is a zero of $F_{ \pm}$if and only if $w=2 b q+\widetilde{w} r$ is a resonance of $H$. Then applying Proposition 9 to $F=F_{+}$and to $F(z)=\overline{F_{-}(-\bar{z})}$ with $h=r, N(r)=n_{+}\left(s_{1} \sqrt{r}, p_{q} W p_{q}\right)|\ln r|$, we obtain existence of functions $g_{0, \pm}$ holomorphic in $\Omega_{ \pm}$such that for $z \in \Omega_{ \pm}$, we have the following factorization

$$
\begin{equation*}
D_{ \pm}\left(\sqrt{r} \sqrt{z}, \sqrt{r} s_{1}\right)=\prod_{w \in \operatorname{Res}(H) \cap 2 b q+r \Omega_{ \pm}}\left(\frac{z r+2 b q-w}{r}\right) \mathrm{e}^{g_{0, \pm}(z, r)} \tag{5.11}
\end{equation*}
$$

with

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} z} g_{0, \pm}(z, r)=\mathcal{O}\left(n_{+}\left(s_{1} \sqrt{r}, p_{q} W p_{q}\right)|\ln r|\right) \tag{5.12}
\end{equation*}
$$

uniformly with respect to $z \in \mathcal{W}_{ \pm}$.
On the other hand, with the notations of Section 3 (see Proposition 4 and the proof of Proposition 5), for $z=z_{q}(\sqrt{r} k), 0<s_{1}<|k|<s_{0}$, we have

$$
\begin{aligned}
& \operatorname{det}_{2}\left((H-z)\left(H_{0}-z\right)^{-1}\right)=\operatorname{det}_{2}\left(I+\mathcal{T}_{V}(z)\right) \\
& =D\left(\sqrt{r} k, \sqrt{r} s_{1}\right) \operatorname{det}\left(\left(I+\frac{i J}{\sqrt{r} k} B_{q} \mathbf{1}_{\left[0, s_{1} \sqrt{r} / 2\right]}\left(B_{q}\right)+\widetilde{A}(k \sqrt{r})\right) \mathrm{e}^{-\mathcal{T}_{V}(z)}\right)
\end{aligned}
$$

By the properties of $\widetilde{A}(k)$ (see the proof of Proposition 5), for $\widetilde{K}(k)=$ $i J /(\sqrt{r} k) B_{q} \mathbf{1}_{\left[0, s_{1} \sqrt{r} / 2\right]}\left(B_{q}\right)+\widetilde{A}(k \sqrt{r})$, the difference $\mathcal{T}_{V}(z)-\widetilde{K}(k)$ is a finiterank operator and as in the proof of (4.1), we have

$$
\begin{aligned}
\operatorname{det}\left(\left(I+\frac{i J}{\sqrt{r} k} B_{q} \mathbf{1}_{\left[0, s_{1} \sqrt{r} / 2\right]}\left(B_{q}\right)+\widetilde{A}(k \sqrt{r})\right) \mathrm{e}^{-\mathcal{T}_{V}(z)}\right) \\
=\operatorname{det}_{2}(I+\widetilde{K}(k)) \mathrm{e}^{-\operatorname{Tr}\left(\mathcal{T}_{V}(z)-\widetilde{K}(k)\right)}
\end{aligned}
$$

where ${\underset{\sim}{\mathcal{A}}}_{2}(I+\widetilde{K}(k))$ is a non-vanishing holomorphic function, for $0<s_{1}<|k|<s_{0}$. Since $\widetilde{A}(k)$ is holomorphic in $S_{2}$ and

$$
\left\|\frac{B_{q}}{s} \mathbf{1}_{[0, s]}\left(B_{q}\right)\right\|_{2}^{2}=-\int_{0}^{s} \frac{u^{2}}{s^{2}} \mathrm{~d} n_{+}\left(u, B_{q}\right)=\widetilde{n}_{2}(s)
$$

we have

$$
\|\widetilde{K}(k)\|_{2}^{2}=\mathcal{O}\left(\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right)\right)
$$

which implies that $\left|\operatorname{det}_{2}(1+\widetilde{K}(k))\right|=\mathcal{O}\left(\exp \left(\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right)\right)\right)$. Using moreover that $\|\widetilde{K}(k)\|<1$, we have also $\left|\operatorname{det}_{2}(1+\widetilde{K}(k))\right|^{-1}=\mathcal{O}\left(\exp \left(\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right)\right)\right)$. Then there exists $g_{1}(., r)$ holomorphic on $\Omega_{ \pm}$such that

$$
\frac{\mathrm{d}}{\mathrm{~d} z} g_{1}(z, r)=\mathcal{O}\left(\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right)\right)
$$

on $\mathcal{W}_{ \pm}$, and

$$
\operatorname{det}_{2}(1+\widetilde{K}(k))=\mathrm{e}^{g_{1}(z, r)}
$$

Then by definition of $\xi_{2}\left(\right.$ see (5.3)), for $\mu=z_{q}(k) \in 2 b q+r\left(\Omega_{ \pm} \cap \mathbb{R}\right)$ we obtain

$$
\begin{aligned}
\xi_{2}^{\prime}(\mu) & =\frac{1}{\pi r} \operatorname{Im} \partial_{\lambda}\left(g_{0, \pm}+g_{1}\right)\left(\frac{\mu-2 b q}{r}, r\right)-\sum_{\substack{w \in \operatorname{Res}(H) \cap 2 b q+r \Omega_{ \pm} \\
\operatorname{Im} w \neq 0}} \frac{-\operatorname{Im} w}{\pi|\mu-w|^{2}} \\
& -\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r I_{ \pm}} \delta(\mu-w) \\
& +\frac{1}{\pi} \operatorname{Im} \operatorname{tr}\left(\frac{1}{2 k} \partial_{k}\left(\frac{i J}{k} B_{q} \mathbf{1}_{\left[0, s_{1} \sqrt{r} / 2\right]}\left(B_{q}\right)+\widetilde{A}(k)\right)-\partial_{z} \mathcal{T}_{V}(\mu+i 0)\right),
\end{aligned}
$$

where

$$
k= \begin{cases}\sqrt{\mu-2 b q} & \text { if } \mu-2 b q>0 \\ i \sqrt{2 b q-\mu} & \text { if } \mu-2 b q<0\end{cases}
$$

According to Lemma 1 and since $B_{q} \in S_{1}$, the operators $\partial_{z} \mathcal{T}_{V}(z)$ and $\partial_{k} \widetilde{A}(k)=\partial_{k} A(k)=\partial_{k}\left(\mathcal{T}_{V}\left(z_{q}(k)\right)-(i / k) J B_{q}\right)$ are of trace class. The trace
of $\partial_{k} A(k)$ is given by the integral of its kernel on the diagonal,

$$
\begin{align*}
\operatorname{tr}\left(\partial_{k} A(k)\right)=\frac{2 k b}{8 \pi} \int_{\mathbb{R}^{3}} V(x) \mathrm{d} x\left(\sum_{j>q}\right. & \left(2 b(j-q)-k^{2}\right)^{-3 / 2}  \tag{5.13}\\
& \left.-i \sum_{j<q}\left(k^{2}+2 b(q-j)\right)^{-3 / 2}\right),
\end{align*}
$$

and by definition of $\widetilde{n}_{1}($ see (3.15))

$$
\operatorname{tr}\left(\frac{1}{2 k} \partial_{k}\left(\frac{i J}{k} B_{q} \mathbf{1}_{\left[0, s_{1} \sqrt{r} / 2\right]}\left(B_{q}\right)\right)\right)=-\frac{i J s_{1} \sqrt{r}}{8 k^{3}} \widetilde{n}_{1}\left(\frac{1}{2} s_{1} \sqrt{r}\right)
$$

Then, we conclude the proof of Proposition 8 with $g_{ \pm}=g_{0, \pm}+g_{1}+g_{2}$ taking

$$
g_{2}(z, r):=\frac{i b}{4 \pi} \int_{\mathbb{R}^{3}} V(x) \mathrm{d} x \sum_{j<q}(z r+2 b(q-j))^{-1 / 2}+\frac{i J s_{1}}{4 \sqrt{z}} \widetilde{n}_{1}\left(\frac{1}{2} s_{1} \sqrt{r}\right)
$$

where $\sqrt{z}$ is defined on $\Omega_{ \pm}$by (5.10).
In the definite-sign case $(J=\operatorname{sign} V)$ we can specify the representation of the regularized spectral shift function when for $z=z_{q}(k)$, the operator $1+(i J / k) B_{q}$ is invertible, that is for $\operatorname{Arg} k \neq-J \frac{1}{2} \pi$. Then we consider $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$open relatively compact subsets of $\left.\pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b[$ with $\varepsilon_{0}>0,2 \theta_{0}+\varepsilon_{0}<2 \pi$ as above, and we have the assumption that

$$
\begin{equation*}
-J \frac{1}{2} \pi \notin\left(\frac{1}{2} \pi\right)_{\mp} \pm\left[-\theta_{0}, \frac{1}{2} \varepsilon_{0}\right] \tag{5.14}
\end{equation*}
$$

where $\left(\frac{1}{2} \pi\right)_{-}=0$ and $\left(\frac{1}{2} \pi\right)_{+}=\frac{1}{2} \pi$. The main restriction is in the case "-" for $V \leqslant 0$ (i.e. $J=-1$ ), where we can consider $\left.\Omega_{-} \subset-\mathrm{e}^{\left.-i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b[$, only with $\theta_{0}<0$, that is where there are no resonances! So in the definitesign case we discuss the three following situations:

- For $V \geqslant 0$, we consider $\left.\mathcal{W}_{+} \subset \subset \Omega_{+} \subset \mathrm{e}^{\left.i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ with $\varepsilon_{0}>0$, $2 \theta_{0}<\pi$ or $\left.\mathcal{W}_{-} \subset \subset \Omega_{-} \subset-\mathrm{e}^{\left.-i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ with $\varepsilon_{0}>0,2 \theta_{0}+\varepsilon_{0}<2 \pi$.
- For $V \leqslant 0$ we consider $\left.\mathcal{W}_{+} \subset \subset \Omega_{+} \subset \mathrm{e}^{\left.i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ with $\varepsilon_{0}>0$, $2 \theta_{0}+\varepsilon_{0}<2 \pi$.

Proposition 10. - Assume $V$ satisfies (2.1) with $m_{\perp}>2$, and is of definite sign $J=\operatorname{sign} V$. Let $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$open relatively compact subsets of $\left.\pm e^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ as above and let the interval $\left.I_{ \pm}=\mathcal{W}_{ \pm} \cap \pm\right] 0,2 b[$. Assume $\theta_{0}$ satisfies (5.14).

Then for $\lambda=\mu-2 b q \in r I_{ \pm}$, the representation (5.8) holds with

$$
\frac{1}{r} \operatorname{Im} g_{ \pm}^{\prime}\left(\frac{\lambda}{r}, r\right)=\frac{1}{r} \operatorname{Im} \widetilde{g}_{ \pm}^{\prime}\left(\frac{\lambda}{r}, r\right)+\operatorname{Im} \widetilde{g}_{1, \pm}^{\prime}(\lambda)+\mathbf{1}_{(0,2 b)}(\lambda) J \Phi^{\prime}(\lambda)
$$

where

$$
\Phi(\lambda):=\operatorname{tr}\left(\arctan \frac{B_{q}}{\sqrt{\lambda}}\right)=\operatorname{tr}\left(\arctan \frac{p_{q} W p_{q}}{2 \sqrt{\lambda}}\right)
$$

$z \mapsto \widetilde{g}_{ \pm}(z, r)$ is holomorphic in $\Omega_{ \pm}$and satisfies

$$
\begin{equation*}
\widetilde{g}_{ \pm}(z, r)=\mathcal{O}(|\ln r|) \tag{5.15}
\end{equation*}
$$

uniformly with respect to $0<r<r_{0}$ and $z \in \mathcal{W}_{ \pm}$while the function $\widetilde{g}_{1, \pm}$ is holomorphic on $\left.\pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ and for $\left.z \in \pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b[$, there exists $C_{\theta_{0}}$ such that

$$
\left|\widetilde{g}_{1, \pm}(z)\right| \leqslant C_{\theta_{0}} \sigma_{2}(\sqrt{|z|})^{1 / 2}
$$

$\sigma_{2}$ being defined in Corollary 1.
Proof. - With the notations of Section 3 (see Proposition 4), and according to relation (4.1), for $z=z_{q}(k), 0<s_{1} \sqrt{r}<|k|<s_{0},-J \operatorname{Im} k<$ $(1 / \delta)|\operatorname{Re} k|$ we have

$$
\begin{aligned}
\operatorname{det}_{2}\left((H-z)\left(H_{0}-z\right)^{-1}\right) & =\operatorname{det}_{2}\left(I+\mathcal{T}_{V}(z)\right) \\
& =\operatorname{det}_{2}(I+K(k)) \operatorname{det}\left(I+\frac{i}{k} J B_{q}\right) \mathrm{e}^{-\operatorname{Tr}\left(\mathcal{T}_{V}(z)-K(k)\right)}
\end{aligned}
$$

with $K(k)=A(k)\left(I+(i / k) J B_{q}\right)^{-1}$. As in the proof of Proposition 8, applying Proposition 9 and the results of Section 4, we obtain existence of functions $\widetilde{g}_{ \pm}$holomorphic in $\Omega_{ \pm}$such that for $z \in \Omega_{ \pm}$, we have the following factorization:

$$
\begin{equation*}
\operatorname{det}_{2}(I+K(\sqrt{r} \sqrt{z}))=\prod_{w \in \operatorname{Res}(H) \cap 2 b q+r \Omega_{ \pm}}\left(\frac{z r+2 b q-w}{r}\right) \mathrm{e}^{\tilde{g}_{ \pm}(z, r)} \tag{5.16}
\end{equation*}
$$

with

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} \lambda} \widetilde{g}_{ \pm}(z, r)=\mathcal{O}(|\ln r|) \tag{5.17}
\end{equation*}
$$

uniformly with respect to $z \in \mathcal{W}_{ \pm}$. Then by definition of $\xi_{2}$ (see (5.3)), for $\mu=z_{q}(k) \in 2 b q+r I_{ \pm}$we obtain

$$
\begin{aligned}
\xi_{2}^{\prime}(\mu)= & \frac{1}{\pi r} \operatorname{Im} \widetilde{g}_{ \pm}^{\prime}\left(\frac{\mu-2 b q}{r}, r\right) \\
& +\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r \Omega_{ \pm}}^{\operatorname{Im} w \neq 0} \frac{\operatorname{Im} w}{\pi|\mu-w|^{2}}-\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r I_{ \pm}} \delta(\mu-w) \\
+ & \frac{1}{2 k \pi} \operatorname{Im} \operatorname{tr}\left(\left(I+\frac{i J}{k} B_{q}\right)^{-1} \partial_{k}\left(\frac{i J}{k} B_{q}\right)\right)-\frac{1}{\pi} \operatorname{Tr}\left(\partial_{z} \mathcal{T}_{V}(\mu)-\frac{1}{2 k} \partial_{k} K(k)\right)
\end{aligned}
$$

where

$$
k= \begin{cases}\sqrt{\mu-2 b q} & \text { if } \mu-2 b q>0 \\ i \sqrt{2 b q-\mu} & \text { if } \mu-2 b q<0\end{cases}
$$

On the other hand, Lemma 1 and Corollary 1 entail that the operators $\partial_{z} \mathcal{T}_{V}(\mu)$ and

$$
\partial_{k} K(k)=\partial_{k} A(k)-\partial_{k}\left(A(k) \frac{i J}{k} B_{q}\left(I+\frac{i J}{k} B_{q}\right)^{-1}\right)
$$

are trace-class. Moreover, from (5.13) and the analyticity of $A$ in $S_{2}$, we have

$$
\operatorname{Im} \frac{1}{2 k} \operatorname{Tr}\left(\partial_{k} K(k)\right)=\operatorname{Im} \frac{1}{2 k} \partial_{k}\left(\widetilde{g}_{1, \pm}\left(k^{2}\right)\right)
$$

with $\widetilde{g}_{1, \pm}$ being the holomorphic function

$$
\begin{aligned}
& \widetilde{g}_{1, \pm}(z):=\frac{i b}{4 \pi} \int_{\mathbb{R}^{3}} V(x) \mathrm{d} x \sum_{j<q}(z+2 b(q-j))^{-1 / 2} \\
&-\operatorname{Tr}\left(A(\sqrt{z}) \frac{i J}{\sqrt{z}} B_{q}\left(I+\frac{i J}{\sqrt{z}} B_{q}\right)^{-1}\right)
\end{aligned}
$$

which satisfies the claimed estimates thanks to (3.12). Finally, we have

$$
\begin{aligned}
\frac{1}{2 k} \operatorname{Im} \operatorname{tr} & \left(\left(I+\frac{i J}{k} B_{q}\right)^{-1} \partial_{k}\left(\frac{i J}{k} B_{q}\right)\right) \\
& =-\frac{1}{2 k^{2}} \operatorname{Im} \operatorname{tr}\left(\frac{i J}{k} B_{q}\left(I+\frac{i J}{k} B_{q}\right)^{-1}\right) \\
& = \begin{cases}0 & \text { for } J k \in i \mathbb{R}^{+} \\
\frac{1}{2 k^{2}} \operatorname{tr}\left(\frac{J}{k} B_{q}\left(I+\frac{B_{q}^{2}}{k^{2}}\right)^{-1}\right)=J \Phi^{\prime}\left(k^{2}\right) & \text { for } k \in \mathbb{R},\end{cases}
\end{aligned}
$$

which prove Proposition 10.
Combining Lemma 8, Proposition 8 and Proposition 10, we deduce BreitWigner approximation of the SSF:

Theorem 3 (Breit-Wigner approximation). - Assume $V$ satisfies (2.1) with $m_{\perp}>2$. Let $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$be open relatively compacts subsets of $\left.\pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ as before Proposition 8 and let $0<s_{1}<\sqrt{\operatorname{dist}\left(\Omega_{ \pm}, 0\right)}$. Then there exists $r_{0}>0$ and functions $g_{ \pm}$holomorphic in $\Omega_{ \pm}$, such that for $\mu \in 2 b q+r I_{ \pm}$, we have

$$
\begin{gather*}
\xi^{\prime}(\mu)=\frac{1}{r \pi} \operatorname{Im} g_{ \pm}^{\prime}\left(\frac{\mu-2 b q}{r}, r\right)+\sum_{\substack{w \in \operatorname{Res}(H) \cap 2 b q+r \Omega_{ \pm} \\
\operatorname{Im} w \neq 0}} \frac{\operatorname{Im} w}{\pi|\mu-w|^{2}}  \tag{5.18}\\
-\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r I_{ \pm}} \delta(\mu-w)
\end{gather*}
$$

where $g_{ \pm}(z, r)$ satisfies the estimate

$$
\begin{align*}
g_{ \pm}(z, r) & =\mathcal{O}\left(n_{+}\left(s_{1} \sqrt{r} ; p_{q} W p_{q}\right)|\ln r|+\widetilde{n}_{1}\left(\frac{1}{2} s_{1} \sqrt{r}\right)+\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right)\right) \\
9) & =\mathcal{O}\left(|\ln r| r^{-1 / m_{\perp}}\right) \tag{5.19}
\end{align*}
$$

uniformly with respect to $0<r<r_{0}$ and $z \in \mathcal{W}_{ \pm}$.
Moreover for potentials of definite sign, $J:=\operatorname{sign} V$, assuming that $\theta_{0}$ satisfies

$$
-J \frac{\pi}{2} \notin\left(\frac{\pi}{2}\right)_{\mp} \pm\left[-\theta_{0}, \frac{\varepsilon_{0}}{2}\right]
$$

(with $\left(\frac{1}{2} \pi\right)_{-}=0$ and $\left.\left(\frac{1}{2} \pi\right)_{+}=\frac{1}{2} \pi\right)$, for $\lambda \in r I_{ \pm}$we have

$$
\frac{1}{r} \operatorname{Im} g_{ \pm}^{\prime}\left(\frac{\lambda}{r}, r\right)=\frac{1}{r} \operatorname{Im} \widetilde{g}_{ \pm}^{\prime}\left(\frac{\lambda}{r}, r\right)+\operatorname{Im} \widetilde{g}_{1, \pm}^{\prime}(\lambda)+\mathbf{1}_{(0,2 b)}(\lambda) J \Phi^{\prime}(\lambda)
$$

where

$$
\Phi(\lambda):=\operatorname{tr}\left(\arctan \frac{B_{q}}{\sqrt{\lambda}}\right)=\operatorname{tr}\left(\arctan \frac{p_{q} W p_{q}}{2 \sqrt{\lambda}}\right)
$$

$z \mapsto \widetilde{g}_{ \pm}(z, r)$ is holomorphic in $\Omega_{ \pm}$and satisfies

$$
\begin{equation*}
\widetilde{g}_{ \pm}(z, r)=\mathcal{O}(|\ln r|) \tag{5.20}
\end{equation*}
$$

uniformly with respect to $0<r<r_{0}$ and $z \in \mathcal{W}_{ \pm}$. The function $\widetilde{g}_{1, \pm}$ is holomorphic on $\left.\pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b\left[\right.$ and for $\left.z \in \pm \mathrm{e}^{\left. \pm i]-2 \theta_{0}, \varepsilon_{0}\right]}\right] 0,2 b[$, there exists $C_{\theta_{0}}$ such that

$$
\begin{equation*}
\left|\widetilde{g}_{1, \pm}(z)\right| \leqslant C_{\theta_{0}} \sigma_{2}(\sqrt{|z|})^{1 / 2} \tag{5.21}
\end{equation*}
$$

$\sigma_{2}$ being defined in Corollary 1.
The following corollary describes the asymptotic behavior of the SSF on the right of a given Landau level.

Corollary 2 (Singularities at the Landau levels). - Assume that $V$ satisfies (2.1) with $m_{\perp}>2$ and is of definite sign: $J=\operatorname{sign} V$. Then the asymptotic relation

$$
\begin{equation*}
\xi(2 b q+\lambda)=\frac{J}{\pi} \Phi(\lambda)+\mathcal{O}\left(\Phi(\lambda)^{1 / 2}\right)+\mathcal{O}\left(|\ln \lambda|^{2}\right) \tag{5.22}
\end{equation*}
$$

holds as $\lambda \searrow 0$.
Proof. - Let us apply Theorem 3 on intervals $2 b q+r_{n}[1,2]$, with $r_{n}=$ $\lambda 2^{n}, \lambda>0$. For $\mu \in 2 b q+r_{n}[1,2]$ and $\Omega_{+}$a complex neighborhood of $[1,2]$,
we have

$$
\begin{align*}
\xi^{\prime}(\mu)= & \frac{1}{r_{n} \pi} \operatorname{Im} \widetilde{g}_{ \pm}^{\prime}\left(\frac{\mu-2 b q}{r_{n}}, r_{n}\right)  \tag{5.23}\\
& +\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r_{n} \Omega_{+}}^{\operatorname{Im} w \neq 0} 0 \\
& \frac{\operatorname{Im} w}{\pi|\mu-w|^{2}}-\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r_{n}[1,2]} \delta(\mu-w) \\
& +\frac{1}{\pi}\left(J \Phi^{\prime}+\operatorname{Im} \widetilde{g}_{1, \pm}^{\prime}\right)(\mu-2 b q) .
\end{align*}
$$

Using that $\int_{\mathbb{R}}-\operatorname{Im} w /\left(\pi|\mu-w|^{2}\right) \mathrm{d} \mu \leqslant 1$ and that $2 b q+r_{n} \Omega_{+}$contains at the most $\mathcal{O}\left(\left|\ln r_{n}\right|\right)$ resonances (see Proposition 6), the integration of (5.23) on $2 b q+r_{n}[1,2]$ yields

$$
\begin{align*}
\xi\left(2 b q+r_{n+1}\right)-\xi\left(2 b q+r_{n}\right)=\frac{1}{\pi}[ & \left.\operatorname{Im} \widetilde{g}_{ \pm}\left(., r_{n}\right)\right]_{1}^{2}+\mathcal{O}\left(\left|\ln r_{n}\right|\right)  \tag{5.24}\\
& +\frac{1}{\pi}\left[J \Phi+\operatorname{Im} \widetilde{g}_{1, \pm}\right]_{r_{n}}^{r_{n+1}}
\end{align*}
$$

Let $N \in \mathbb{N}$ such that $\frac{1}{2} b \leqslant \lambda 2^{N+1} \leqslant b($ then $N=\mathcal{O}(|\ln \lambda|))$. Since $\xi, \Phi$ and $\widetilde{g}_{1, \pm}$ are uniformly bounded on $2 b q+b[1 / 2,1]$ ( $b$ the fixed strength of the magnetic field), and since $\widetilde{g}_{ \pm}\left(., r_{n}\right)=\mathcal{O}\left(\left|\ln r_{n}\right|\right)$, taking the sum of (5.24) from $n=0$ to $n=N$, we have

$$
\xi(2 b q+\lambda)=\frac{J}{\pi} \Phi(\lambda)+\frac{1}{\pi} \operatorname{Im} \widetilde{g}_{1, \pm}(\lambda)+\sum_{n=0}^{N} \mathcal{O}\left(\left|\ln \left(2^{n} \lambda\right)\right|\right)+\mathcal{O}(1)
$$

Using (5.21) and exploiting that $N=\mathcal{O}(|\ln \lambda|)$, we obtain existence of $C>0$ such that

$$
\left|\xi(2 b q+\lambda)-\frac{J}{\pi} \Phi(\lambda)\right| \leqslant C|\ln \lambda|^{2}+C \sigma_{2}(\sqrt{\lambda})^{1 / 2}
$$

Then Corollary 2 follows from the elementary inequality

$$
\frac{u^{2}}{1+u^{2}} \leqslant \arctan u, \quad u \geqslant 0
$$

which implies $\sigma_{2}(\sqrt{\lambda}) \leqslant \Phi(\lambda)$.
Let us compare our results with those of [11] where the singularities of the SSF at a given Landau level were investigated.

If $W$ satisfies the assumptions of Lemmas 3, 4 or 5 (plus some generic technical assumptions in the case of a rapid decay), then it is shown in [11] that

$$
\begin{equation*}
\xi(2 b q+\lambda)=\frac{J}{\pi} \Phi(\lambda)(1+o(1)), \quad \lambda \searrow 0 \tag{5.25}
\end{equation*}
$$

In the case of slowly decaying $W$ satisfying the assumptions of Lemma 3, we see that (5.22) provides a remainder estimate of asymptotic relation (5.25). In the case of rapidly decaying $W$ (see Lemma 4 or Lemma 5) we have

$$
\Phi(\lambda)=\frac{1}{2} \varphi_{\beta}(\lambda)(1+o(1)), \quad \lambda \searrow 0
$$

Hence, in the case $\beta \in] 0, \frac{1}{2}$ [ relation (5.22) again provides a remainder estimate of (5.25). However, in the case $\beta \in\left[\frac{1}{2}, \infty\right]$ it does not even recover the first asymptotic term of (5.25). Note also that in [11] the decay of $V$ is assumed to be isotropic in all three directions while here we assume that $V$ is super-exponentially decaying with respect to $x_{3}$.

On the left of Landau level, for $V \geqslant 0$, the results of [11] imply that $\xi(2 b q-\lambda)=\mathcal{O}(1)$. Here our estimates are not accurate to see this. For $V \leqslant 0$, it is shown in [11] that

$$
\xi(2 b q-\lambda)=n_{+}\left(2 \sqrt{\lambda} ; p_{q} W p_{q}\right)(1+o(1)), \quad \lambda \searrow 0
$$

In this case, we have only general representation formula (5.18) with estimate (5.19).

As in [21], (or [6]), from Theorem 3 we deduce also the following trace formula.

Corollary 3 (Trace formula). - Let $\mathcal{W}_{ \pm} \subset \subset \Omega_{ \pm}$be as in Theorem 3. Suppose that $f_{ \pm}$is holomorphic on a neighborhood of $\Omega_{ \pm}$and that $\psi_{ \pm} \in$ $C_{0}^{\infty}\left(\Omega_{ \pm} \cap \mathbb{R}\right)$ satisfies $\psi_{ \pm}(\lambda)=1$ near $\mathcal{W}_{ \pm} \cap \mathbb{R}$. Then under the assumptions of Theorem 3 we have the following trace formula

$$
\begin{align*}
& \operatorname{tr}\left(\left(\psi_{ \pm} f_{ \pm}\right)\left(\frac{H-2 b q}{r}\right)-\left(\psi_{ \pm} f_{ \pm}\right)\left(\frac{H_{0}-2 b q}{r}\right)\right)  \tag{5.26}\\
& \quad=\sum_{w \in \operatorname{Res}(H) \cap 2 b q+r \mathcal{W}_{ \pm}} f_{ \pm}\left(\frac{w-2 b q}{r}\right)+E_{f_{ \pm}, \psi_{ \pm}}(r)
\end{align*}
$$

with

$$
\left|E_{f_{ \pm}, \psi_{ \pm}}(r)\right| \leqslant M\left(\psi_{ \pm}\right) \sup \left\{\left|f_{ \pm}(z)\right|: z \in \Omega_{ \pm} \backslash \mathcal{W}_{ \pm}, \operatorname{Im} z \leqslant 0\right\} \times N_{q}(r)
$$

where

$$
\begin{aligned}
N_{q}(r) & =n_{+}\left(s_{1} \sqrt{r} ; p_{q} W p_{q}\right)|\ln r|+\widetilde{n}_{1}\left(\frac{1}{2} s_{1} \sqrt{r}\right)+\widetilde{n}_{2}\left(\frac{1}{2} s_{1} \sqrt{r}\right) \\
& =\mathcal{O}\left(|\ln r| r^{-1 / m_{\perp}}\right)
\end{aligned}
$$

Proof. - In the proof we omit the subscript $\pm$. Choose an almost analytic extension $\widetilde{\psi}$ of $\psi$ so that $\widetilde{\psi} \in C_{0}^{\infty}(\Omega), \widetilde{\psi}=1$ on $\mathcal{W}$ and

$$
\operatorname{supp} \bar{\partial}_{z} \tilde{\psi} \subset \Omega \backslash \mathcal{W}
$$

Applying Theorem 3, we have

$$
\begin{aligned}
& \operatorname{tr}\left((\psi f)\left(\frac{H-2 b q}{r}\right)-(\psi f)\left(\frac{H_{0}-2 b q}{r}\right)\right) \\
& =-\left\langle\xi^{\prime}(\lambda),(\psi f)\left(\frac{\lambda-2 b q}{r}\right)\right\rangle \\
& =\sum_{w \in \operatorname{Res}(H) \mathrm{n} 2 b q+r \operatorname{supp} \psi}(\psi f)\left(\frac{w-2 b q}{r}\right) \\
& \quad-\frac{1}{r \pi} \int(\psi f)\left(\frac{\lambda-2 b q}{r}\right) \operatorname{Im} g^{\prime}\left(\frac{\lambda-2 b q}{r}, r\right) \mathrm{d} \lambda \\
& \quad+\frac{1}{2 \pi i} \int(\psi f)\left(\frac{\lambda-2 b q}{r}\right) \\
& \quad \times \sum_{\substack{ \\
w \in \operatorname{Res}(H) \cap 2 b q+r \operatorname{supp} \widetilde{\psi} \\
\operatorname{Im} w \neq 0}}\left(\frac{1}{\lambda-w}-\frac{1}{\lambda-\bar{w}}\right) \mathrm{d} \lambda .
\end{aligned}
$$

The integral involving $g^{\prime}$ can be estimated using (5.19) on supp $\widetilde{\psi}$. For the integral related to the resonances, we apply the Green formula and we get the term

$$
\begin{aligned}
& \sum_{w \in \operatorname{Res}(H), \operatorname{Im} w \neq 0}(\widetilde{\psi} f)\left(\frac{w-2 b q}{r}\right) \\
& +\frac{1}{r \pi} \int_{\mathbb{C}_{-}}\left(\bar{\partial}_{z} \widetilde{\psi}\right)\left(\frac{z-2 b q}{r}\right) f\left(\frac{z-2 b q}{r}\right) \\
& \times \sum_{\substack{w \in \operatorname{Res}(H) \cap 2 b q+r \operatorname{supp} \widetilde{\psi} \\
\operatorname{Im} w \neq 0}}\left(\frac{1}{z-\bar{w}}-\frac{1}{z-w}\right) L(\mathrm{~d} z) .
\end{aligned}
$$

We apply the inequality

$$
\int_{\Omega_{1}} \frac{1}{|z-w|} L(\mathrm{~d} z) \leqslant 2 \sqrt{2 \pi\left|\Omega_{1}\right|}
$$

and the upper bound of the resonances in $\Omega$ contained in Theorem 1, to obtain the result.

Acknowledgments. - The authors would like to thank the referee for the helpful suggestions concerning the descriptions of the subsets of $\mathcal{M}$.
