# On Cubics and Quartics Through a Canonical Curve 

CHRISTIAN PAULY

#### Abstract

We construct families of quartic and cubic hypersurfaces through a canonical curve, which are parametrized by an open subset in a Grassmannian and a Flag variety respectively. Using G. Kempf's cohomological obstruction theory, we show that these families cut out the canonical curve and that the quartics are birational (via a blowing-up of a linear subspace) to quadric bundles over the projective plane, whose Steinerian curve equals the canonical curve.

Mathematics Subject Classification (2000): 14H60 (primary), 14H42 (secondary).

## 1. - Introduction

Let $C$ be a smooth nonhyperelliptic curve of genus $g \geq 4$ defined over the complex numbers, which we consider as an embedded curve $\iota_{\omega}: C \hookrightarrow \mathbb{P}^{g-1}$ by its canonical linear series $|\omega|$. Let $I=\bigoplus_{n \geq 2} I(n)$ be the graded ideal of the canonical curve. It was classically known (Noether-Enriques-Petri theorem, see e.g. [ACGH] p. 124) that the ideal $I$ is generated by its elements of degree 2 , unless $C$ is trigonal or a plane quintic.

It was also classically known how to construct some distinguished quadrics in $I(2)$. We consider a double point of the theta divisor $\Theta \subset \operatorname{Pic}^{g-1}(C)$, which corresponds by Riemann's singularity theorem to a degree $g-1$ line bundle $L$ satisfying $\operatorname{dim}|L|=\operatorname{dim}\left|\omega L^{-1}\right|=1$ and we observe that the morphism $\iota_{L} \times \iota_{\omega L^{-1}}: C \longrightarrow C^{\prime} \subset|L|^{*} \times\left|\omega L^{-1}\right|^{*}=\mathbb{P}^{1} \times \mathbb{P}^{1}$ (here $C^{\prime}$ denotes the image curve) followed by the Segre embedding into $\mathbb{P}^{3}$ factorizes through the canonical space $|\omega|^{*}$, i.e.,

where $\pi$ is projection from a $(g-5)$-dimensional vertex $\mathbb{P} V^{\perp}$ in $|\omega|^{*}$. We then
define the quadric $Q_{L}:=\pi^{-1}\left(\mathbb{P}^{1} \times \mathbb{P}^{1}\right)$, which is a rank $\leq 4$ quadric in $I(2)$ and coincides with the projectivized tangent cone at the double point $[L] \in \Theta$ under the identification of $H^{0}(C, \omega)^{*}$ with the tangent space $T_{[L]} \operatorname{Pic}^{g-1}(C)$. The main result, due to M . Green [Gr], asserts that the set of quadrics $\left\{Q_{L}\right\}$, when $L$ varies over the double points of $\Theta$, linearly spans $I(2)$. From this result one infers a constructive Torelli theorem by intersecting all quadrics $Q_{L}$ - at least for $C$ general enough.

The geometry of the theta divisor $\Theta$ at a double point [ $L$ ] can also be exploited to produce higher degree elements in the ideal $I$ as follows: we expand in a suitable set of coordinates a local equation $\theta$ of $\Theta$ near [ $L$ ] as $\theta=\theta_{2}+\theta_{3}+\ldots$, where $\theta_{i}$ are homogeneous forms of degree $i$. Having seen that $Q_{L}=\operatorname{Zeros}\left(\theta_{2}\right)$, we denote by $S_{L}$ the cubic $\operatorname{Zeros}\left(\theta_{3}\right) \subset|\omega|^{*}$, the osculating cone of $\Theta$ at $[L]$. The cubic $S_{L}$ has many nice geometric properties: under the blowing-up of the vertex $\mathbb{P} V^{\perp} \subset S_{L}$, the cubic $S_{L}$ is transformed into a quadric bundle $\tilde{S}_{L}$ over $\mathbb{P}^{1} \times \mathbb{P}^{1}$ and it was shown by G. Kempf and F.-O. Schreyer [KS] that the Hessian and Steinerian curves of $\tilde{S}_{L}$ are $C^{\prime} \subset \mathbb{P}^{1} \times \mathbb{P}^{1}$ and $C \subset|\omega|^{*}$ respectively, which gives another proof of Torelli's theorem.

In this paper we construct and study distinguished cubics and quartics in the ideal $I$ by adapting the methods of $[\mathrm{KS}]$ to rank- 2 vector bundles over $C$. Our construction basically goes as follows (Section 2): we consider a general 3-plane $W \subset H^{0}(C, \omega)$ and define the rank-2 vector bundle $E_{W}$ as the dual of the kernel of the evaluation map in $\omega$ of sections of $W$. The bundle $E_{W}$ is stable and admits a theta divisor $D\left(E_{W}\right)$ in the Jacobian $J C$. Since $D\left(E_{W}\right)$ contains the origin $\mathcal{O} \in J C$ with multiplicity 4 , the projectivized tangent cone to $D\left(E_{W}\right)$ at $\mathcal{O}$ is a quartic hypersurface in $\mathbb{P} T_{\mathcal{O}} J C=|\omega|^{*}$, denoted by $F_{W}$ and which contains the canonical curve. We therefore obtain a rational map from the Grassmannian $\operatorname{Gr}\left(3, H^{0}(\omega)\right)$ to the ideal of quartics $|I(4)|$

$$
\begin{equation*}
\mathbf{F}_{4}: \operatorname{Gr}\left(3, H^{0}(\omega)\right) \rightarrow|I(4)|, \quad W \mapsto F_{W} \tag{1.1}
\end{equation*}
$$

Our main tool to study the tangent cones $F_{W}$ is G. Kempf's cohomological obstruction theory [K1], [K2], [KS] which in our set-up leads to a simple criterion (Proposition 4.1) for $b \in \mathbb{P} T_{\mathcal{O}} J C=|\omega|^{*}$ to belong to $F_{W}$. We deduce in particular from this criterion that the cubic polar $P_{x}\left(F_{W}\right)$ of $F_{W}$ with respect to a point $x \in W^{\perp}$ also contains the canonical curve. Here $W^{\perp}$ denotes the annihilator of $W \subset H^{0}(\omega)$. We therefore obtain a rational map from the flag variety $\mathrm{Fl}\left(3, g-1, H^{0}(\omega)\right)$ parametrizing pairs $(W, x)$ to the ideal of cubics |I(3)|

$$
\begin{equation*}
\mathbf{F}_{3}: \mathrm{Fl}\left(3, g-1, H^{0}(\omega)\right) \rightarrow|I(3)|, \quad(W, x) \mapsto P_{x}\left(F_{W}\right) . \tag{1.2}
\end{equation*}
$$

Our two main results can be stated as follows.
(1) Like the cubic osculating cones $S_{L}$, the quartic tangent cones $F_{W}$ transform under the blowing-up of the vertex $\mathbb{P} W^{\perp} \subset F_{W}$ into a quadric bundle $\tilde{F}_{W} \rightarrow \mathbb{P} W^{*}=\mathbb{P}^{2}$. Their Hessian and Steinerian curves are the plane curve
$\Gamma$, image under the projection with center $\mathbb{P} W^{\perp}, \pi: C \rightarrow \Gamma \subset \mathbb{P} W^{*}$, and the canonical curve $C \subset|\omega|^{*}$ (Theorem 4.8). This surprising analogy with the osculating cones $S_{L}$ remains however unexplained.
(2) Let us denote by $\left|F_{4}\right| \subset|I(4)|$ and $\left|F_{3}\right| \subset|I(3)|$ the linear subsystems spanned by the quartics $F_{W}$ and the cubics $P_{x}\left(F_{W}\right)$ respectively. Then we show (Theorem 6.1) that both base loci of $\left|F_{4}\right|$ and $\left|F_{3}\right|$ coincide with $C \subset|\omega|^{*}$,i.e., the quartics $F_{W}$ (resp. the cubics $P_{x}\left(F_{W}\right)$ ) cut out the canonical curve.

The starting point of our investigations was the question asked by B. van Geemen and G. van der Geer ([vGvG] page 629) about "these mysterious quartics" which arise as tangent cones to $2 \theta$-divisors in the Jacobian having multiplicity $\geq 4$ at the origin. In that paper the authors implicitly conjectured that the base locus of $\left|F_{4}\right|$ equals $C$, which was subsequently proved by G. Welters [We]. Our proof follows from the fact that $\left|F_{4}\right|$ contains all squares of quadrics in $|I(2)|$.

This paper leaves many questions unanswered (Section 7), like e.g. finding explicit equations of the quartics $F_{W}$, their syzygies, the dimensions of $\left|F_{3}\right|$ and $\left|F_{4}\right|$. The techniques used here also apply when replacing $|\omega|^{*}$ by Prymcanonical space $|\omega \alpha|^{*}$, and generalizing rank-2 vector bundles to symplectic bundles.

Acknowledgements. Many results contained in this paper arose from discussions with Bert van Geemen, whose influence on this work is considerable. I would like to thank him for these enjoyable and valuable discussions.

## 2. - Some constructions for rank-2 vector bundles with canonical determinant

In this section we briefly recall some known results from [BV], [vGI] and [PP] on rank-2 vector bundles over $C$.

## 2.1. - Bundles $E$ with $\operatorname{dim} H^{0}(C, E) \geq 3$

Let $W \subset H^{0}(C, \omega)$ be a 3-plane. We denote by $[W] \in \operatorname{Gr}\left(3, H^{0}(\omega)\right)$ the corresponding point in the Grassmannian and by $\mathcal{B} \subset \operatorname{Gr}\left(3, H^{0}(\omega)\right)$ the codimension 2 subvariety consisting of $[W]$ such that the net $\mathbb{P} W \subset|\omega|$ has a base point. For $[W] \notin \mathcal{B}$ we consider (see [vGI] Section 4) the rank-2 vector bundle $E_{W}$ defined by the exact sequence

$$
\begin{equation*}
0 \longrightarrow E_{W}^{*} \longrightarrow \mathcal{O}_{C} \otimes W \xrightarrow{e v} \omega \longrightarrow 0 . \tag{2.1}
\end{equation*}
$$

Here $E_{W}^{*}$ denotes the dual bundle of $E_{W}$. We have $\operatorname{det} E_{W}=\omega$ and $W^{*} \subset$ $H^{0}\left(C, E_{W}\right)$. We denote by $\mathcal{D}$ the effective divisor in $\left|\mathcal{O}_{\mathrm{Gr}}(g-2)\right|$ defined by the condition

$$
[W] \in \mathcal{D} \Longleftrightarrow \operatorname{dim} H^{0}\left(C, E_{W}\right) \geq 4
$$

We have the inclusion $\mathcal{B} \subset \mathcal{D}$. If $[W] \notin \mathcal{D}$, then $E_{W}$ is stable ([vGI] Lemma 4.2).

Let $W^{\perp} \subset H^{0}(\omega)^{*}=H^{1}(\mathcal{O})$ denote the annihilator of $W \subset H^{0}(\omega)$. We call the projective subspace $\mathbb{P} W^{\perp} \subset|\omega|^{*}$ the vertex and denote by

$$
\pi:|\omega|^{*} \rightarrow \mathbb{P} W^{*}, \quad \pi: C \rightarrow \Gamma \subset \mathbb{P} W^{*}
$$

the projection with center $\mathbb{P} W^{\perp}$. Abusing notation we also denote by $\pi$ a linear lift $\pi: H^{0}(\omega)^{*} \rightarrow W^{*}$. If $[W] \notin \mathcal{B}$, then $C \cap \mathbb{P} W^{\perp}=\emptyset$ and $\pi$ restricts to a morphism $C \rightarrow \mathbb{P} W^{*}$. Its image is a plane curve $\Gamma$ of degree $2 g-2$. We note that $E_{W}=\pi^{*}(T(-1))$, where $T$ is the tangent bundle of $\mathbb{P} W^{*}=\mathbb{P}^{2}$.

Conversely any globally generated bundle $E$ with $\operatorname{det} E=\omega$ is of the form $E_{W}$.
2.2. - Bundles $E$ with $\operatorname{dim} H^{0}(C, E) \geq 4$

Following [BV] (see also [PP] Section 5.2) we associate to a bundle $E$ with $\operatorname{dim} H^{0}(C, E)=4$ a rank $\leq 6$ quadric $Q_{E} \in|I(2)|$, which is defined as the inverse image of the Klein quadric under the dual $\mu^{*}$ of the exterior product map

$$
\mu^{*}:|\omega|^{*} \longrightarrow \mathbb{P}\left(\Lambda^{2} H^{0}(E)^{*}\right) \supset \operatorname{Gr}\left(2, H^{0}(E)^{*}\right), \quad Q_{E}:=\left(\mu^{*}\right)^{-1}(\mathrm{Gr})
$$

Composing with the previous construction, we obtain a rational map

$$
\alpha: \mathcal{D} \rightarrow|I(2)|, \quad \alpha([W])=Q_{E_{W}}
$$

Moreover given a $Q \in|I(2)|$ with $\operatorname{rk} Q \leq 6$ and $\operatorname{Sing} Q \cap C=\emptyset$, it is easily shown that

$$
\alpha^{-1}(Q)=\left\{[W] \in \mathcal{D} \mid \mathbb{P} W^{\perp} \subset Q\right\}
$$

If rk $Q=6$, then $\alpha^{-1}(Q)$ has two connected components, which are isomorphic to $\mathbb{P}^{3}$.

Lemma 2.1. We have $[W] \notin \mathcal{D}$ if and only if the linear map induced by restricting quadrics to the vertex $\mathbb{P} W^{\perp}$

$$
\text { res }: I(2) \longrightarrow H^{0}\left(\mathbb{P} W^{\perp}, \mathcal{O}(2)\right)
$$

is an isomorphism.
Proof. It is enough to observe that the two spaces have the same dimension and that a nonzero element in ker res corresponds to a $Q \in|I(2)|$ with $\mathrm{rk} Q \leq 6$.

## 2.3. - Definition of the quartic $F_{W}$

We will now define the main object of this paper. Given $[W] \notin \mathcal{B}$, we consider the $2 \theta$-divisor $D\left(E_{W}\right) \subset J C$ (see e.g. [BV], [vGI], [PP]), whose settheoretical support equals

$$
D\left(E_{W}\right)=\left\{\xi \in J C \mid \operatorname{dim} H^{0}\left(C, \xi \otimes E_{W}\right)>0\right\}
$$

Since $\operatorname{mult}_{\mathcal{O}} D\left(E_{W}\right) \geq \operatorname{dim} H^{0}\left(C, E_{W}\right) \geq 3$ and since any $2 \theta$-divisor is symmetric, the first nonzero term of the Taylor expansion of a local equation of $D\left(E_{W}\right)$ at the origin $\mathcal{O}$ is a homogeneous polynomial $F_{W}$ of degree 4. The hypersurface in $|\omega|^{*}=\mathbb{P} T_{\mathcal{O}} J C$ associated to $F_{W}$ is also denoted by $F_{W}$. Here we restrict attention to the case $\operatorname{dim} H^{0}\left(C, E_{W}\right)=3$ or 4 . We have

$$
F_{W}:=\operatorname{Cone}_{\mathcal{O}}\left(D\left(E_{W}\right)\right) \subset|\omega|^{*} .
$$

The study of the quartics $F_{W}$ for $[W] \in \operatorname{Gr}\left(3, H^{0}(\omega)\right) \backslash \mathcal{D}$ is the main purpose of this paper. If $[W] \in \mathcal{D}$, the quartics $F_{W}$ have already been described in [PP] Proposition 5.12.

Proposition 2.2. If $\operatorname{dim} H^{0}\left(C, E_{W}\right)=4$, then $F_{W}$ is a double quadric

$$
F_{W}=Q_{E_{W}}^{2}
$$

Since $|I(2)|$ is linearly spanned by rank $\leq 6$ quadrics (see [PP] Section 5), we obtain the following fact, which will be used in Section 6.

Proposition 2.3. The linear subsystem $\left|F_{4}\right|$ contains all squares of quadrics in | $I(2) \mid$.

Although we will not use that fact, we mention that the rational map (1.1) is given by a linear subsystem $\Pi \subset\left|\mathcal{J}_{\mathcal{B}}(g-1)\right|$, where $\mathcal{J}_{\mathcal{B}}$ is the ideal sheaf of the subvariety $\mathcal{B}$. If $g=4$, the inclusion is an equality (see [OPP] Section 6). If $g>4$, a description of $\Pi$ is not known.

## 3. - Kempf's cohomological obstruction theory

In this section we outline Kempf's deformation theory [K1] and apply it to the study of the tangent cones $F_{W}$ of the divisors $D\left(E_{W}\right)$.

## 3.1. - Variation of cohomology

Let $\mathcal{E}$ be a vector bundle over the product $C \times S$, where $S=\operatorname{Spec}(A)$ is an affine neighbourhood of the origin of $J C$. We restrict attention to the case

$$
\mathcal{E}=\pi_{C}^{*} E_{W} \otimes \mathcal{L}
$$

for some 3-plane $W$, and recall that Kempf's deformation theory was applied [K1], [K2], [KS] to the case $\mathcal{E}=\pi_{C}^{*} M \otimes \mathcal{L}$, for a line bundle $M$ over $C$. The line bundle $\mathcal{L}$ denotes the restriction of a Poincaré line bundle over $C \times J C$ to the neighbourhood $C \times S$. The fundamental idea to study the variation of cohomology, i.e., the two upper-semicontinuous functions on $S$

$$
s \mapsto h^{0}\left(C \times\{s\}, \mathcal{E} \otimes_{A} \mathbb{C}_{s}\right), \quad s \mapsto h^{1}\left(C \times\{s\}, \mathcal{E} \otimes_{A} \mathbb{C}_{s}\right),
$$

where $\mathbb{C}_{s}=A / \mathfrak{m}_{s}$ and $\mathfrak{m}_{s}$ is the maximal ideal of $s \in S$, is based on the existence of an approximating homomorphism.

Theorem 3.1 (Grothendieck, [K1] Section 7). Given a family $\mathcal{E}$ of vector bundles over $C \times S$, there exist two flat $A$-modules $F$ and $G$ of finite type and an $A$ homomorphism $\alpha: F \rightarrow G$ such that for all $A$-modules $M$, we have isomorphisms
$H^{0}\left(C \times S, \mathcal{E} \otimes_{A} M\right) \cong \operatorname{ker}\left(\alpha \otimes_{A} i d_{M}\right), \quad H^{1}\left(C \times S, \mathcal{E} \otimes_{A} M\right) \cong \operatorname{coker}\left(\alpha \otimes_{A} i d_{M}\right)$.
By considering a smaller neighbourhood of the origin, we may assume the $A$-modules $F$ and $G$ to be locally free (Nakayama's lemma). Moreover ([K1] Lemma 10.2) by restricting further the neighbourhood, we may find an approximating homomorphism $\alpha: F \rightarrow G$ such that $\alpha \otimes \mathbb{C}_{0}: F \otimes_{A} A / \mathfrak{m}_{0} \rightarrow$ $G \otimes_{A} A / \mathfrak{m}_{0}$ is the zero homomorphism.

We apply this theorem to the family $\mathcal{E}=\pi_{C}^{*} E_{W} \otimes \mathcal{L}$, for [ $W$ ] $\notin \mathcal{D}$. Since by Riemann-Roch $\chi\left(\mathcal{E} \otimes \mathbb{C}_{s}\right)=\chi\left(E_{W} \otimes \mathcal{L}_{s}\right)=0, \forall s \in S$, and since $h^{0}\left(C, E_{W}\right)=3$, the local equation $f$ of the divisor

$$
D\left(E_{W}\right)_{\mid S}=\left\{s \in S: \mid: h^{0}\left(C \times\{s\}, E_{W} \otimes \mathcal{L}_{s}\right)>0\right\}
$$

is given at the origin $\mathcal{O}$ by the determinant of a $3 \times 3$ matrix of regular functions $f_{i j}$ on $S$, with $1 \leq i, j \leq 3$, which vanish at $\mathcal{O}$, i.e., the $A$-modules $F$ and $G$ are free and of rank 3. Hence

$$
f=\operatorname{det}\left(f_{i j}\right)
$$

The linear part of the regular functions $f_{i j}$ is related to the cup-product as follows ([K1] Lemma 10.3 and Lemma 10.6): let $\mathfrak{m}=\mathfrak{m}_{0}$ be the maximal ideal of the origin $\mathcal{O} \in S$ and consider the exact sequence of $A$-modules

$$
0 \longrightarrow \mathfrak{m} / \mathfrak{m}^{2} \longrightarrow A / \mathfrak{m}^{2} \longrightarrow A / \mathfrak{m} \longrightarrow 0
$$

After tensoring with $\mathcal{E}$ over $C \times S$ and taking cohomology, we obtain a coboundary map

$$
\begin{aligned}
H^{0}\left(C, E_{W}\right) & =H^{0}\left(C \times\{s\}, \mathcal{E} \otimes_{A} A / \mathfrak{m}\right) \stackrel{\delta}{\longrightarrow} H^{1}\left(C \times\{s\}, \mathcal{E} \otimes_{A} \mathfrak{m} / \mathfrak{m}^{2}\right) \\
& =H^{1}\left(C, E_{W}\right) \otimes \mathfrak{m} / \mathfrak{m}^{2}
\end{aligned}
$$

where $\mathfrak{m} / \mathfrak{m}^{2}$ is the Zariski cotangent space at $\mathcal{O}$ to $J C$. Note that we have a canonical isomorphism $\left(\mathfrak{m} / \mathfrak{m}^{2}\right)^{*} \cong H^{1}(\mathcal{O})$ and that a tangent vector $b \in H^{1}(\mathcal{O})$ gives, by composing with the linear form $l_{b}: \mathfrak{m} / \mathfrak{m}^{2} \rightarrow \mathbb{C}$, a linear map $\delta_{b}$ : $H^{0}\left(E_{W}\right) \rightarrow H^{1}\left(E_{W}\right)$. As in the line bundle case [K1], one proves

Lemma 3.2. For any nonzero $b \in H^{1}(\mathcal{O})=T_{\mathcal{O}} J C$, we have

1. The linear map $\delta_{b}: H^{0}\left(E_{W}\right) \rightarrow H^{1}\left(E_{W}\right)$ coincides with the cup-product $(\cup b)$ with the class $b$, and is skew-symmetric after identifying $H^{1}\left(E_{W}\right)$ with $H^{0}\left(E_{W}\right)^{*}$ (Serre duality).
2. The coboundary map $\delta: H^{0}\left(E_{W}\right) \rightarrow H^{1}\left(E_{W}\right) \otimes \mathfrak{m} / \mathfrak{m}^{2}$ is described by a skew-symmetric $3 \times 3$ matrix $\left(x_{i j}\right)$, with $x_{i j} \in H^{1}(\mathcal{O})^{*}$. Moreover the linear form $x_{i j}$ coincides with the differential $\left(d f_{i j}\right)_{0}$ of $f_{i j}$ at the origin $\mathcal{O}$.
The coboundary map $\delta$ induces a linear map

$$
\Delta: H^{1}(\mathcal{O}) \longrightarrow \Lambda^{2} H^{0}\left(E_{W}\right)^{*}, \quad b \longmapsto \delta_{b}
$$

which coincides with the dual of the multiplication map of global sections of $E_{W}$. Moreover

$$
\operatorname{ker} \Delta=W^{\perp}=\left\{x_{12}=x_{13}=x_{23}=0\right\}
$$

Using a flat structure [K2] we can write the power series expansion of the regular functions $f_{i j}$ around $\mathcal{O}$

$$
f_{i j}=x_{i j}+q_{i j}+\ldots
$$

where $x_{i j}$ and $q_{i j}$ are linear and quadratic polynomials respectively. We easily calculate the expansion of $f$ : by skew-symmetry its cubic term is zero, and its quartic term equals
$F_{W}: q_{11} x_{23}^{2}+q_{22} x_{13}^{2}+q_{33} x_{12}^{2}+x_{12} x_{23}\left(q_{13}+q_{31}\right)-x_{12} x_{23}\left(q_{12}+q_{21}\right)-x_{12} x_{13}\left(q_{23}+q_{32}\right)$.
We straightforwardly deduce from this equation the following properties of $F_{W}$.

## Proposition 3.3.

1. The quartic $F_{W}$ is singular along the vertex $\mathbb{P} W^{\perp}$.
2. For any $x \in W^{\perp}$, the cubic polar $P_{x}\left(F_{W}\right)$ is singular along the vertex $\mathbb{P} W^{\perp}$.

## 3.2. - Infinitesimal deformations of global sections of $E_{W}$

We first recall some elementary facts on principal parts. Let $V$ be an arbitrary vector bundle over $C$ and let $\operatorname{Rat}(V)$ be the space of rational sections of $V$ and $p$ be a point of $C$. The space of principal parts of $V$ at $p$ is the quotient

$$
\operatorname{Prin}_{p}(V)=\operatorname{Rat}(V) / \operatorname{Rat}_{p}(V),
$$

where $\operatorname{Rat}_{p}(V)$ denotes the space of rational sections of $V$ which are regular at $p$. Since a rational section of $V$ has only finitely many poles, we have a natural mapping

$$
\begin{equation*}
\operatorname{pp}: \operatorname{Rat}(V) \longrightarrow \operatorname{Prin}(V):=\bigoplus_{p \in C} \operatorname{Prin}_{p}(V), \quad s \longmapsto\left(s \quad \bmod \operatorname{Rat}_{p}(V)\right)_{p \in C} \tag{3.1}
\end{equation*}
$$

Exactly as in the line bundle case ([K1] Lemma 3.3), one proves

Lemma 3.4. There are isomorphisms

$$
\text { ker } \mathrm{pp} \cong H^{0}(C, V), \quad \text { coker } \mathrm{pp} \cong H^{1}(C, V)
$$

In the particular case $V=\mathcal{O}$, we see that a tangent vector $b \in H^{1}(\mathcal{O})=$ $T_{\mathcal{O}} J C$ can be represented by a collection $\beta=\left(\beta_{p}\right)_{p \in I}$ of rational functions $\beta_{p} \in \operatorname{Rat}(\mathcal{O})$, where $p$ varies over a finite set of points $I \subset C$. We then define $\operatorname{pp}(\beta)=\left(\omega_{p}\right)_{p \in I} \in \operatorname{Prin}(\mathcal{O})$, where $\omega_{p}$ is the principal part of $\beta_{p}$ at $p$. We denote by $[\beta]=b$ its cohomology class in $H^{1}(\mathcal{O})$. Note that we can define powers of $\beta$ by $\beta^{k}:=\left(\beta_{p}^{k}\right)_{p \in I}$.

For $i \geq 1$, let $D_{i}$ be the infinitesimal scheme $\operatorname{Spec}\left(A_{i}\right)$, where $A_{i}$ is the Artinian ring $\mathbb{C}[\epsilon] / \epsilon^{i+1}$. As explained in [K2] Section 2, a tangent vector $b \in H^{1}(\mathcal{O})$ determines a morphism

$$
\exp _{i, b}: D_{i} \longrightarrow J C,
$$

with $\exp _{i, b}\left(x_{0}\right)=\mathcal{O}$, where $x_{0}$ is the closed point of $D_{i}$. Let $\mathbb{L}_{i+1}(b)$ denote the pull-back of the Poincaré sheaf $\mathcal{L}$ under the morphism $\exp _{i, b} \times i d_{C}$. Note that we have the following exact sequences

$$
\begin{array}{r}
D_{1} \times C: \quad 0 \longrightarrow \epsilon \mathcal{O} \longrightarrow \mathbb{L}_{2}(b) \longrightarrow \mathcal{O} \longrightarrow 0 \\
D_{2} \times C: \quad 0 \longrightarrow \epsilon^{2} \mathcal{O} \longrightarrow \mathbb{L}_{3}(b) \longrightarrow \mathbb{L}_{2}(b) \longrightarrow 0 \tag{3.3}
\end{array}
$$

The second arrows in each sequence correspond to the restriction to the subschemes $\left\{x_{0}\right\} \times C \subset D_{1} \times C$ and $D_{1} \times C \subset D_{2} \times C$ respectively. As above we choose a representative $\beta$ of $b$. Following [K2] Section 2, one shows that the space of global sections $H^{0}\left(C \times D_{i}, \mathbb{L}_{i+1}(b) \otimes E\right)$, with $E=E_{W}$ and $[W] \notin \mathcal{D}$, is isomorphic to the $A_{i}$-module

$$
\begin{align*}
& V_{i}(\beta)=\left\{f=f_{0}+\ldots+f_{i} \epsilon^{i} \in \operatorname{Rat}(E) \otimes A_{i}\right.  \tag{3.4}\\
&\text { such that } f \exp (\epsilon \beta) \text { is regular } \forall p \in C\} .
\end{align*}
$$

An element $f \in V_{i}(\beta)$ is called an $i$-th order deformation of the global section $f_{0} \in H^{0}(E)$. In the case $i=2$, the condition $f \in V_{i}(\beta)$ is equivalent to the following three elements,

$$
\begin{equation*}
f_{0}, \quad f_{1}+f_{0} \beta, \quad f_{2}+f_{1} \beta+f_{0} \frac{\beta^{2}}{2} \tag{3.5}
\end{equation*}
$$

being regular at all points $p \in C-$ for $i=1$, we consider the first two elements. Alternatively this means that their classes in $\operatorname{Prin}(E)$ are zero. We note that, given two representatives $\beta=\left(\beta_{p}\right)_{p \in I}$ and $\beta^{\prime}=\left(\beta_{p}^{\prime}\right)_{p \in I^{\prime}}$ with $[\beta]=\left[\beta^{\prime}\right]$, the two subspaces $V_{i}(\beta)$ and $V_{i}\left(\beta^{\prime}\right)$ of $\operatorname{Rat}(E) \otimes A_{i}$ are different and that any rational function $\varphi \in \operatorname{Rat}(\mathcal{O})$ satisfying $\operatorname{pp}(\varphi)=\operatorname{pp}\left(\beta^{\prime}-\beta\right)$ induces an isomorphism $V_{i}(\beta) \cong V_{i}\left(\beta^{\prime}\right)$.

We consider a class $b \in H^{1}(\mathcal{O}) \backslash W^{\perp}$ and a representative $\beta$ such that $[\beta]=b$. By taking cohomology of (3.2) tensored with $E$, we observe that a first order deformation of $f_{0}$, i.e., a global section $f=f_{0}+f_{1} \epsilon \in V_{1}(\beta) \cong$ $H^{0}\left(C \times D_{1}, \mathbb{L}_{2}(b) \otimes E\right)$ always exists. Since $\operatorname{rk}(\cup b)=2$, the global section $f_{0}$ is uniquely determined up to a scalar

$$
f_{0} \cdot \mathbb{C}=\operatorname{ker}\left(\cup b: H^{0}(E) \longrightarrow H^{1}(E)\right)
$$

Moreover any two first order deformations of $f_{0}$ differ by an element in $\epsilon H^{0}(E)$.
We now state a criterion for a tangent vector $b=[\beta]$ to lie on the quartic tangent cone $F_{W}$ in terms of a second order deformation of $f_{0} \in H^{0}(E)$.

Lemma 3.5. A cohomology class $b=[\beta] \in H^{1}(\mathcal{O}) \backslash W^{\perp}$ is contained in the cone over the quartic $F_{W}$ if and only if there exists a global section

$$
f=f_{0}+f_{1} \epsilon+f_{2} \epsilon^{2} \in V_{2}(\beta) \cong H^{0}\left(C \times D_{2}, \mathbb{L}_{3}(b) \otimes E\right)
$$

Proof. The proof is similar to [KS] Lemma 4. We work over the Artinian ring $A_{4}$, i.e., $\epsilon^{5}=0$. By Theorem 3.1 applied to the family $\mathbb{L}_{5}(b) \otimes E$ over $C \times D_{4}$, there exists an approximating homomorphism of $A_{4}$-modules

$$
\begin{equation*}
A_{4}^{\oplus 3} \xrightarrow{\varphi} A_{4}^{\oplus 3}, \tag{3.6}
\end{equation*}
$$

such that $\operatorname{ker} \varphi_{\mid D_{2}} \cong H^{0}\left(C \times D_{2}, \mathbb{L}_{3}(b) \otimes E\right)$, coker $\varphi_{\mid D_{2}} \cong H^{1}\left(C \times D_{2}, \mathbb{L}_{3}(b) \otimes E\right)$, and $\varphi \otimes \mathbb{C}_{0}=0$. We denote by $\varphi_{\mid D_{2}}$ the homomorphism obtained from (3.6) by projecting to $A_{2}$. Note that any $A_{4}$-module is free. The matrix $\varphi$ is equivalent to a matrix

$$
M:=\left(\begin{array}{ccc}
\epsilon^{u} & 0 & 0 \\
0 & \epsilon^{v} & 0 \\
0 & 0 & \epsilon^{w}
\end{array}\right)
$$

Since $\varphi \otimes \mathbb{C}_{0}=0$, we have $u, v, w \geq 1$. Moreover we can order the exponents so that $1 \leq u \leq v \leq w$. It follows from the definition of $D\left(E_{W}\right)$ as a determinant divisor that the pull-back of $D\left(E_{W}\right)$ by $\exp _{4}: D_{4} \longrightarrow J C$ is given by the equation (in $A_{4}$ )

$$
\operatorname{det} M=\epsilon^{u+v+w}
$$

We immediately see that $b \in F_{W}$ if and only if $u+v+w \geq 5$. Let us now restrict $\varphi$ to $D_{1}$,i.e., we project (3.6) to $A_{1}$. Since we assume $b \notin W^{\perp}=\operatorname{ker} \Delta$, the restriction $\varphi_{\mid D_{1}}$ is nonzero and by skew-symmetry of rank 2 , i.e., $u=v=1$ and $w \geq 2$. Hence $b \in F_{W}$ if and only if $w \geq 3$.

On the other hand the $A_{2}$-module $\operatorname{ker} \varphi_{\mid D_{2}} \cong H^{0}\left(C \times D_{2}, \mathbb{L}_{3}(b) \otimes E\right)$ has length $2+w$. Let $\mu$ be the multiplication by $\epsilon^{2}$ on this $A_{2}$-module. Then by (3.4) the $A_{2}$-module $\operatorname{ker} \mu$ is isomorphic to the $A_{1}$-module $H^{0}\left(C \times D_{1}, \mathbb{L}_{2}(b) \otimes E\right)$, which is of length 4 , provided $b \notin W^{\perp}$. Hence we obtain that $w \geq 3$ if and only if there exists an $f \in H^{0}\left(C \times D_{2}, \mathbb{L}_{3}(b) \otimes E\right)$ such that $\mu(f)=\epsilon^{2} f_{0}$. This proves the lemma.

## 4. - Study of the quartic $F_{W}$

In this section we prove geometric properties of the quartic $F_{W}$.

## 4.1. - Criteria for $b \in F_{W}$

We now show that the criterion of Lemma 3.5 simplifies to a criterion involving only a first order deformation $f=f_{0}+f_{1} \epsilon \in V_{1}(\beta)$ of $f_{0}$. As above we assume $b \notin W^{\perp}$.

First we observe that the rational differential form $f_{1} \wedge f_{0}$ is independent of the choice of the representative $\beta$, i.e., $f_{1} \wedge f_{0}$ only depends on the cohomology class $b=[\beta]$ : suppose we take $\beta^{\prime}=\left(\beta_{p} \cdot \varphi\right)_{p \in I}$, where $\varphi \in \operatorname{Rat}(\omega)$. Then $f_{0}$ and $f_{1}$ transform into $f_{0}^{\prime}=f_{0}$ and $f_{1}^{\prime}=f_{1}+\varphi f_{0}$, from which it is clear that $f_{1}^{\prime} \wedge f_{0}^{\prime}=f_{1} \wedge f_{0}$.

Secondly one easily sees that $f_{0}=\pi(b)$ (Section 2.1) and that, under the canonical identification $\Lambda^{2} W^{*}=\Lambda^{2} H^{0}(E)=W$, the 2-plane $H^{0}(E) \wedge f_{0}$ coincides with the intersection $V_{b}:=H_{b} \cap W$, where $H_{b}$ denotes the hyperplane determined by $b \in H^{1}(\mathcal{O})$.

It follows from these two remarks that, given $b$ and $W$, the form $f_{1} \wedge f_{0}$ is well-defined up to a regular differential form in $V_{b} \subset W$.

Proposition 4.1. We have the following equivalence

$$
b \in F_{W} \quad \Longleftrightarrow \quad f_{1} \wedge f_{0} \in H_{b}
$$

Proof. Since $f_{1} \wedge f_{0}$ does not depend on $\beta$, we may choose a $\beta$ with simple poles at the points $p \in I$. By Lemma 3.5 and relation (3.5) we see that $b \in F_{W}$ if and only if the cohomology class $\left[f_{1} \beta+f_{0} \frac{\beta^{2}}{2}\right]$ is zero in $H^{1}(E) / \operatorname{im}(\cup b)-$ we recall that $f_{1}$ is defined up to $H^{0}(E)$.

First we will prove that $\left[f_{0} \frac{\beta^{2}}{2}\right] \in \operatorname{im}(\cup b)$. The commutativity of the upper right triangle of the diagram (see e.g. [K1])

$$
\begin{array}{ccc}
H^{0}(E) & \\
\downarrow \cdot \frac{\beta^{2}}{2} & \searrow & \cup\left[\frac{\beta^{2}}{2}\right] \\
H^{0}(E) \longrightarrow H^{0}(E(2 I)) \longrightarrow E(2 I)_{\mid 2 I} & \longrightarrow & H^{1}(E) \\
\cap & \cap & \nearrow \\
\operatorname{Rat}(E) & \xrightarrow{\mathrm{pp}} \operatorname{Prin}(E)
\end{array}
$$

implies that $\left[f_{0} \frac{\beta^{2}}{2}\right]=f_{0} \cup\left[\frac{\beta^{2}}{2}\right]$. Moreover the skew-symmetric cup-product map $\cup b$

$$
\cup b=\wedge \bar{b}: H^{0}(E)=W^{*} \longrightarrow H^{1}(E)=W=\Lambda^{2} W^{*}
$$

identifies with the exterior product $\wedge \bar{b}$, where $\bar{b}=\pi(b) \in W^{*}$. It is clear that $\operatorname{im}(\cup b)=\operatorname{im}(\wedge \bar{b})=\operatorname{ker}(\wedge \bar{b})$, where $\wedge \bar{b}$ also denotes the linear form

$$
\begin{equation*}
\wedge \bar{b}: \Lambda^{2} W^{*} \longrightarrow \Lambda^{3} W^{*} \cong \mathbb{C} \tag{4.1}
\end{equation*}
$$

As already observed, we have $f_{0}=\bar{b}$. Denoting by $c \in W^{*}$ the class $\pi\left(\left[\frac{\beta^{2}}{2}\right]\right)$, we see that the relation $\left(f_{0} \wedge c\right) \wedge \bar{b}=\bar{b} \wedge c \wedge \bar{b}=0$ implies that $f_{0} \cup\left[\frac{\beta^{2}}{2}\right] \in$ $\operatorname{ker}(\wedge \bar{b})=\operatorname{im}(\cup b)$.

Therefore the previous condition simplifies to $\left[f_{1} \beta\right] \in \operatorname{im}(\cup b)$. We next observe that the linear form $\wedge \bar{b}$ on $H^{1}(E)$ (4.1) identifies with the exterior product map

$$
H^{1}(E) \xrightarrow{\wedge f_{0}} H^{1}(\omega) \cong \mathbb{C} .
$$

Since we have a commutative diagram

$$
\begin{array}{r}
f_{1} \in \quad H^{0}(E(I)) \xrightarrow{\cdot \beta} \operatorname{Prin}(E) \longrightarrow H^{1}(E) \\
\downarrow \wedge f_{0} \\
\downarrow \wedge f_{0} \\
f_{1} \wedge f_{0} \in H^{0}(\omega) \xrightarrow{\cdot \beta} \operatorname{Prin}(\omega) \longrightarrow H^{1}(\omega),
\end{array}
$$

and since $f_{1} \wedge f_{0} \in H^{0}(\omega) \subset \operatorname{Rat}(\omega)$, we easily see that the condition $\left[f_{1} \beta\right] \in$ $\operatorname{im}(\cup b)$ is equivalent to $f_{1} \wedge f_{0} \in H_{b}=\operatorname{ker}\left(\cup b: H^{0}(\omega) \longrightarrow H^{1}(\omega)\right)$.

In the following proposition we give more details on the element $f_{1} \wedge f_{0} \in$ $H^{0}(\omega)$. We additionally assume that $\pi(b) \notin \Gamma$, which implies that the global section $f_{0} \in H^{0}(E)$ does not vanish at any point and hence determines an exact sequence

$$
\begin{equation*}
0 \longrightarrow \mathcal{O} \xrightarrow{f_{0}} E \xrightarrow{\wedge f_{0}} \omega \longrightarrow 0 \tag{4.2}
\end{equation*}
$$

The coboundary map of the associated long exact sequence

$$
\begin{equation*}
\cdots \longrightarrow H^{0}(\omega) \xrightarrow{\cup e} H^{1}(\mathcal{O}) \longrightarrow \cdots \tag{4.3}
\end{equation*}
$$

is symmetric and coincides (e.g. [K1] Corollary 6.8) with cup-product $\cup e$ with the extension class $e \in \mathbb{P} H^{1}\left(\omega^{-1}\right)=\left|\omega^{2}\right|^{*}$. Moreover $\cup e$ is the image of $e$ under the dual of the multiplication map

$$
\begin{equation*}
H^{1}\left(\omega^{-1}\right)=H^{0}\left(\omega^{2}\right)^{*} \hookrightarrow \operatorname{Sym}^{2} H^{0}(\omega)^{*}, \quad e \longmapsto \cup e . \tag{4.4}
\end{equation*}
$$

We note that $\operatorname{corank}(\cup e)=2$ and that $\operatorname{ker}(\cup e)=V_{b}$. Hence $\left(f_{1} \wedge f_{0}\right) \cup e$ is well-defined.

Proposition 4.2. If $\pi(b) \notin \Gamma$, then $f_{1} \wedge f_{0} \notin \operatorname{ker}(\cup e)$ and we have (up to a nonzero scalar)

$$
\left(f_{1} \wedge f_{0}\right) \cup e=b \in H^{1}(\mathcal{O})
$$

Proof. We keep the notation of the previous proof. The condition $f_{1} \wedge f_{0} \in$ $V_{b}$ implies that $f_{1}$ is a regular section and, by (3.5), that $f_{0}$ vanishes at the support of $b$, i.e., $\pi(b) \in \Gamma$. As for the equality of the proposition, we introduce the rank-2 vector bundle $\hat{E}$ which is obtained from $E$ by (positive) elementary transformations at the points $p \in I$ and with respect to the line in $E_{p}$ spanned by the nonzero vector $f_{0}(p)$. Then we have $E \subset \hat{E} \subset E(I)$ and $\hat{E}$ fits into the exact sequence

$$
0 \longrightarrow E \longrightarrow \hat{E} \longrightarrow \mathcal{O}_{I} \longrightarrow 0
$$

Moreover $f_{1} \in H^{0}(\hat{E})$, which follows from condition (3.5). We also have the following exact sequences

$$
\begin{gather*}
0 \longrightarrow \mathcal{O}(I) \longrightarrow \hat{E} \xrightarrow{\wedge f_{0}} \omega \longrightarrow 0  \tag{e}\\
\cup \cup \quad \cup  \tag{e}\\
0 \longrightarrow \mathcal{O} \xrightarrow{f_{0}} E \xrightarrow{\wedge f_{0}} \omega \longrightarrow 0
\end{gather*}
$$

and the extension class $\hat{e} \in H^{1}\left(\omega^{-1}(D)\right)$ is obtained from $e$ by the canonical projection $H^{1}\left(\omega^{-1}\right) \rightarrow H^{1}\left(\omega^{-1}(I)\right)$. Taking the associated long exact sequences, we obtain

$$
f_{1} \in H^{0}(\hat{E}) \xrightarrow{\wedge f_{0}} H^{0}(\omega) \xrightarrow{\cup \hat{e}} H^{1}(\mathcal{O}(I))
$$

$$
\begin{array}{cc}
\cup & \begin{array}{c}
\| \\
H_{I} \\
H^{0}(E) \xrightarrow{\wedge f_{0}}
\end{array} H^{0}(\omega) \xrightarrow{\cup e} \\
H^{1}(\mathcal{O}),
\end{array}
$$

where the two squares commute. This means that

$$
\pi_{I}\left(\left(f_{1} \wedge f_{0}\right) \cup e\right)=\left(f_{1} \wedge f_{0}\right) \cup \hat{e}=0
$$

Since $f_{1} \wedge f_{0}$ does not depend on $\beta$ (nor on $I$ ), the latter relation holds for any $I$ with $I=\operatorname{supp} \beta$. Hence, denoting by $\langle I\rangle$ the linear span in $|\omega|^{*}$ of the support $I$ of $\beta$, we obtain

$$
\left(f_{1} \wedge f_{0}\right) \cup e \in \bigcap_{I=\operatorname{supp} \beta} \operatorname{ker} \pi_{I}=\bigcap_{b \in\langle I\rangle}\langle I\rangle=b .
$$

## 4.2. - Geometric properties of $F_{W}$

Proposition 4.3. For any $[W] \notin \mathcal{D}$ we have the following

1. The quartic $F_{W}$ contains the canonical curve $C$, i.e., $F_{W} \in|I(4)|$.
2. The quartic $F_{W}$ contains the secant line $\overline{p q}$, with $p \neq q$, if and only if $\overline{p q} \cap$ $\mathbb{P} W^{\perp} \neq \emptyset$ or $\operatorname{dim} W \cap H^{0}(\omega(-2 p-2 q))>0$.
3. Let $\Sigma$ be the set of points $p$ at which the tangent line $\mathbb{T}_{p}(C)$ intersects the vertex $\mathbb{P} W^{\perp}$. Then $\Sigma$ is empty for general $[W]$ and finite for any $[W]$. Moreover any point $p \in C \backslash \Sigma$ is smooth on $F_{W}$ and the embedded tangent space $\mathbb{T}_{p}\left(F_{W}\right)$ is the linear span of $\mathbb{T}_{p}(C)$ and $\mathbb{P} W^{\perp}$.

Proof. All statements are easily deduced from Proposition 4.1. Given a point $p \in C$ we denote by $\mathfrak{p}_{p} \in \operatorname{Prin}_{p}(\mathcal{O})$ the principal part supported at $p$ of a rational function with a simple pole at $p$. Then the class $\left[p_{p}\right] \in H^{1}(\mathcal{O})$ is proportional to $i_{\omega}(p) \in|\omega|^{*}=\mathbb{P} H^{1}(\mathcal{O})$ and the section $f_{0}$ vanishes at $p$. Hence $f_{0} \mathfrak{p}_{p} \in \operatorname{Prin}(E)$ is everywhere regular and we may choose $f_{1}=0$. This proves part 1. See also [PP].

As for part 2, we introduce $\beta_{\lambda, \mu}=\lambda \mathfrak{p}_{p}+\mu \mathfrak{p}_{q} \in \operatorname{Prin}(\mathcal{O})$ for $\lambda, \mu \in \mathbb{C}$ and denote by $s_{p}$ and $s_{q}$ the global sections $\pi\left(\left[p_{p}\right]\right)$ and $\pi\left(\left[p_{q}\right]\right)$, which vanish at $p$ and $q$ respectively. Then one checks that $f_{0}=\lambda s_{p}+\mu s_{q} \in \operatorname{ker}\left(\cup\left[\beta_{\lambda, \mu}\right]\right)$ and $\mathrm{pp}\left(f_{1}\right)=\lambda \mu\left(s_{q} \mathfrak{p}_{p}+s_{p} \mathfrak{p}_{q}\right) \in \operatorname{Prin}(E)$. With this notation the condition of Proposition 4.1 transforms into

$$
\begin{equation*}
0=l_{\lambda, \mu}\left(f_{0} \wedge f_{1}\right)=\lambda \mu\left(\lambda^{2} \gamma_{p}+\mu^{2} \gamma_{q}\right) \tag{4.5}
\end{equation*}
$$

where $l_{\lambda, \mu}$ is the linear form defined by $\left[\beta_{\lambda, \mu}\right] \in H^{1}(\mathcal{O})$. The scalars $\gamma_{p}$ and $\gamma_{q}$ are the values of the section $s_{p} \wedge s_{q} \in W \cap H^{0}(\omega(-p-q))$ at $p$ and $q$ respectively. We now conclude noting that $s_{p} \wedge s_{q}=0$ if and only if $\overline{p q} \cap \mathbb{P} W^{\perp} \neq \emptyset$.

As for part 3, we first observe that the assumption $\Sigma=C$ implies that the restriction $\pi_{\mid C}: C \rightarrow \mathbb{P} W^{*}$ contracts $C$ to a point, which is impossible. Next we consider the tangent vector $t_{q}$ at $p$ given by the direction $q$. By putting $\lambda=1$ and $\mu=\epsilon$, with $\epsilon^{2}=0$, into equation (4.5) we obtain that $t_{q} \in \mathbb{T}_{p}\left(F_{W}\right)$ if and only if $\epsilon \gamma_{p}=0$, i.e., $\pi(q) \in \mathbb{T}_{\pi(p)}(\Gamma)$. Hence $\mathbb{T}_{p}\left(F_{W}\right)=\pi^{-1}\left(\mathbb{T}_{\pi(p)}(\Gamma)\right)$, which proves part 3 .

## 4.3. - The cubic polar $P_{x}\left(F_{W}\right)$

Firstly we deduce from Propositions 4.1 and 4.2 a criterion for $b \in P_{x}\left(F_{W}\right)$, with $x \in W^{\perp}$. Let $H_{x}$ be the hyperplane determined by $x \in H^{1}(\mathcal{O})$. As above we assume $b \notin W^{\perp}$ and $\pi(b) \notin \Gamma$, i.e., the pencil $V=V_{b}$ is base-point-free.

Proposition 4.4. We have the following equivalence

$$
b \in P_{x}\left(F_{W}\right) \quad \Longleftrightarrow \quad f_{1} \wedge f_{0} \in H_{x}
$$

Proof. We recall from Section 4.1 that $\cup e$ induces a symmetric isomorphism $\cup e:\left(V^{\perp}\right)^{*} \xrightarrow{\sim} V^{\perp}$ and we denote by $Q^{*} \subset \mathbb{P}\left(V^{\perp}\right)^{*}$ and $Q \subset \mathbb{P} V^{\perp}$ the two associated smooth quadrics. Note that $Q$ and $Q^{*}$ are dual to each other. Combining Propositions 4.1, 4.2 and 3.3 (1) we see that the restriction of the quartic $F_{W}$ to the linear subspace $\mathbb{P} V^{\perp} \subset|\omega|^{*}$ splits into a sum of divisors

$$
\left(F_{W}\right)_{\mid \mathbb{P} V^{\perp}}=2 \mathbb{P} W^{\perp}+Q
$$

We also observe that $Q$ only depends on $V$ (and on $W$ ) and not on $b$. Taking the polar with respect to $x \in W^{\perp}$, we obtain

$$
\left(P_{x}\left(F_{W}\right)\right)_{\mid \mathbb{P} V^{\perp}}=2 \mathbb{P} W^{\perp}+P_{x}(Q)
$$

Finally we see that the condition $b \in P_{x}(Q)$ is equivalent to $f_{0} \wedge f_{1}=$ $(\cup e)^{-1}(b) \in H_{x}$.

We easily deduce from this criterion some properties of $P_{x}\left(F_{W}\right)$.
Proposition 4.5. The cubic $P_{x}\left(F_{W}\right)$ contains the canonical curve $C$, i.e., $P_{x}\left(F_{W}\right) \in|I(3)|$.

Proof. We first observe that the two closed conditions of Proposition 4.4 are equivalent outside $\pi^{-1}(\Gamma)$. Hence they coincide as well on $\pi^{-1}(\Gamma)$ and we can drop the assumption $\pi(b) \notin \Gamma$. Now, as in the proof of Proposition 4.3 (1), we may choose $f_{1}=0$.

Proposition 4.6. We have the following properties

$$
\begin{gathered}
\bigcap_{x \in W^{\perp}} P_{x}\left(F_{W}\right)=S_{W} \cup \mathbb{P} W^{\perp} \cup \bigcup_{n \geq 2} \Lambda_{n}, \\
F_{W} \cap S_{W}=C \cup \Lambda_{1}, \quad \text { and } \quad \Lambda:=\bigcup_{n \geq 0} \Lambda_{n} \subset F_{W},
\end{gathered}
$$

where $S_{W}$ is an irreducible surface. For $n \geq 0$, we denote by $\Lambda_{n}$ the union of $(n+1)$ secant $\mathbb{P}^{n \prime}$ s to the canonical curve $C$, which intersect the vertex $\mathbb{P} W^{\perp}$ along a $\mathbb{P}^{n-1}$. If $W$ is general, then $\Lambda_{n}=\emptyset$ for $n \geq 2$ and $\Lambda_{1}$ is the union of $2(g-1)(g-3)$ secant lines.

Proof. We consider $b$ in the intersection of all $P_{x}\left(F_{W}\right)$ and we first suppose that $\pi(b) \notin \Gamma$. Then by Propositions 4.1 and 4.4 we have

$$
f_{0} \wedge f_{1} \in \bigcap_{x \in W^{\perp}} H_{x}=W
$$

Hence we obtain that $\mathbb{P} V^{\perp} \cap \bigcap_{x \in W^{\perp}} P_{x}\left(F_{W}\right)$ is reduced to the point $(\cup e)(W) \in$ $\mathbb{P} V^{\perp}$. On the other hand a standard computation shows that $S_{W}$ is the image of $\mathbb{P}^{2}$ under the linear system of the adjoint curves of $\Gamma$. Hence $S_{W}$ is irreducible.

If $\pi(b) \in \Gamma$, we denote by $p_{1}, \ldots, p_{n+1} \in C$ the points such that $\pi\left(p_{i}\right)=$ $\pi(b)$. Then $f_{0}$ vanishes at $p_{1}, \ldots, p_{n+1}$. Since $f_{1} \wedge f_{0}$ does not depend on the support of $b$, we can choose $\operatorname{supp} b$ such that $p_{i} \notin \operatorname{supp} b$. Then $f_{1}$ is regular at $p_{i}$ and we deduce that $f_{1} \wedge f_{0} \in H^{0}\left(\omega\left(-\sum p_{i}\right)\right) \cap W=V_{b}$. Now any rational $f_{1}$ satisfying $f_{1} \wedge f_{0} \in V_{b}=\operatorname{im}\left(\wedge f_{0}\right)$ is regular everywhere, which can only happen when $f_{0}$ vanishes at the support of $b$. By uniqueness we have $\operatorname{supp} b \subset\left\{p_{1}, \ldots, p_{n+1}\right\}$ and $b \in \Lambda_{n}$. Note that $\Lambda_{0}=C$. This proves the first equality.

If $b \in F_{W} \cap S_{W}$, we have $f_{1} \wedge f_{0} \in W \cap H_{b}=V_{b}$ and we conclude as above. Note that $\Lambda_{1}$ is contained in $S_{W}$ and is mapped by $\pi$ to the set of ordinary double points of $\Gamma$.

For any $[W] \in \operatorname{Gr}\left(3, H^{0}(\omega)\right) \backslash \mathcal{D}$ we introduce the subspace of $I(3)$

$$
L_{W}=\left\{R \in I(3) \mid R \text { is singular along the vertex } \mathbb{P} W^{\perp}\right\}
$$

Then Propositions 4.5 and 3.3 (2) imply that $P_{x}\left(F_{W}\right) \in L_{W}$. More precisely, we have

Proposition 4.7. The restriction of the polar map of the quartic $F_{W}$ to its vertex $\mathbb{P} W^{\perp}$

$$
\mathbf{P}: W^{\perp} \longrightarrow L_{W}, \quad x \longmapsto P_{x}\left(F_{W}\right)
$$

is an isomorphism.
Proof. First we show that $\operatorname{dim} L_{W}=g-3$. We choose a complementary subspace $A$ to $W^{\perp}$,i.e., $H^{0}(\omega)^{*}=W^{\perp} \oplus A$, and a set of coordinates $x_{1}, \ldots, x_{g-3}$ on $W^{\perp}$ and $a_{1}, a_{2}, a_{3}$ on $A$. This enables us to expand a cubic $F \in S^{3} H^{0}(\omega)$

$$
\begin{gathered}
F=F_{3}(x)+F_{2}(x) G_{1}(a)+F_{1}(x) G_{2}(a)+G_{3}(a), \\
F_{i} \in \mathbb{C}\left[x_{1}, \ldots, x_{g-3}\right], G_{i} \in \mathbb{C}\left[a_{1}, a_{2}, a_{3}\right]
\end{gathered}
$$

with $\operatorname{deg} F_{i}=\operatorname{deg} G_{i}=i$. Let $\mathcal{S}_{A}$ denote the subspace of cubics singular along $\mathbb{P} A$,i.e. $G_{2}=G_{3}=0$. We consider the linear map

$$
\alpha: I(3) \longrightarrow \mathcal{S}_{A}, \quad F \longmapsto F_{3}(x)+F_{2}(x) G_{1}(a) .
$$

Since by Lemma 2.1 any monomial $x_{i} x_{j} \in H^{0}\left(\mathbb{P} W^{\perp}, \mathcal{O}(2)\right)$ lifts to a quadric $Q_{i j} \in I(2)$, we observe that the monomials $x_{i} x_{j} x_{k}$ and $x_{i} x_{j} a_{l}$, which generate $\mathcal{S}_{A}$, also lift e.g. to $Q_{i j} x_{k}$ and $Q_{i j} a_{l}$ in $I(3)$. Hence $\alpha$ is surjective and $\operatorname{dim} L_{W}=\operatorname{dim} \operatorname{ker} \alpha$ is easily calculated. One also checks that this computation does not depend on $A$.

In order to conclude, it will be enough to show that $\mathbf{P}$ is injective. Suppose that the contrary holds, i.e., there exists a point $x \in W^{\perp}$ with $P_{x}\left(F_{W}\right)=0$. Given any base-point-free pencil $V \subset W$ and any $b \in V^{\perp}$, we obtain by Proposition 4.4 that $f_{0} \wedge f_{1} \in H_{x}$. Since $\cup e:\left(V^{\perp}\right)^{*} \xrightarrow{\sim} V^{\perp}$ is an isomorphism, we see that for $b \notin(\cup e)^{-1}\left(H_{x}\right)$ the element $f_{0} \wedge f_{1}$ must be zero. This implies that $b \in \Lambda$ and since $b$ varies in an open subset of $|\omega|^{*}$, we obtain $\Lambda=|\omega|^{*}$, a contradiction.

## 4.4. - The quadric bundle associated to $F_{W}$

Let $\tilde{\mathbb{P}}_{W}^{g-1} \rightarrow|\omega|^{*}$ denote the blowing-up of $|\omega|^{*}$ along the vertex $\mathbb{P} W^{\perp} \subset$ $|\omega|^{*}$. The rational projection $\pi:|\omega|^{*} \rightarrow \mathbb{P}^{2}=\mathbb{P} W^{*}$ resolves into a morphism $\tilde{\pi}: \tilde{\mathbb{P}}_{W}^{g-1} \rightarrow \mathbb{P}^{2}$. Since $F_{W}$ is singular along $\mathbb{P} W^{\perp}$ (Proposition 3.3 (2)), the proper transform $\tilde{F}_{W} \subset \tilde{\mathbb{P}}_{W}^{g-1}$ admits a structure of a quadric bundle $\tilde{\pi}: \tilde{F}_{W} \rightarrow$ $\mathbb{P}^{2}$.

The contents of Propositions 4.3 and 4.5 can be reformulated in a more geometrical way.

Theorem 4.8. For any $[W] \in \operatorname{Gr}\left(3, H^{0}(\omega)\right) \backslash \mathcal{D}$, the quadric bundle $\tilde{\pi}: \tilde{F}_{W} \rightarrow$ $\mathbb{P}^{2}$ has the following properties

1. Its Hessian curve is $\Gamma \subset \mathbb{P}^{2}$.
2. Its Steinerian curve is the (proper transform of the) canonical curve $C \subset|\omega|^{*}$.
3. The rational Steinerian map $\mathrm{St}: \Gamma \rightarrow C$, which associates to a singular quadric its singular point, coincides with the adjoint map ad of the plane curve $\Gamma$. Moreover the closure of the image $\operatorname{ad}\left(\mathbb{P}^{2}\right)$ equals $S_{W}$.

Remark 4.9. We note that Theorem 4.8 is analogous to the main result of $[\mathrm{KS}]$ (replace $\mathbb{P}^{2}$ with $\mathbb{P}^{1} \times \mathbb{P}^{1}$ ). In spite of this striking similarity and the relation between the two parameter spaces Sing and $\operatorname{Gr}\left(3, H^{0}(\omega)\right)$ (see [PP]), we were unable to find a common frame for both constructions.

## 5. - The cubic hypersurface $\Psi_{V} \subset \mathbb{P}^{g-3}$ associated to a base-point-free pencil $\mathbb{P} V \subset|\omega|$

In this section we show that the symmetric cup-product maps $\cup e \in$ $\operatorname{Sym}^{2} H^{0}(\omega)^{*}$ (see (4.3)) arise as polar quadrics of a cubic hypersurface $\Psi_{V}$, which will be used in the proof of Theorem 6.1.

Let $V$ denote a base-point-free pencil of $H^{0}(\omega)$. We consider the exact sequence given by evaluation of sections of $V$

$$
\begin{equation*}
0 \longrightarrow \omega^{-1} \longrightarrow \mathcal{O}_{C} \otimes V \xrightarrow{e v} \omega \longrightarrow 0 \tag{5.1}
\end{equation*}
$$

Its extension class $v \in \operatorname{Ext}^{1}\left(\omega, \omega^{-1}\right) \cong H^{1}\left(\omega^{-2}\right) \cong H^{0}\left(\omega^{3}\right)^{*}$ corresponds to the hyperplane in $H^{0}\left(\omega^{3}\right)$, which is the image of the multiplication map

$$
\begin{equation*}
\operatorname{im}\left(V \otimes H^{0}\left(\omega^{2}\right) \longrightarrow H^{0}\left(\omega^{3}\right)\right) \tag{5.2}
\end{equation*}
$$

We consider the cubic form $\Psi_{V}$ defined by

$$
\Psi_{V}: \operatorname{Sym}^{3} H^{0}(\omega) \xrightarrow{\mu} H^{0}\left(\omega^{3}\right) \xrightarrow{\bar{v}} \mathbb{C},
$$

where $\mu$ is the multiplication map and $\bar{v}$ the linear form defined by the extension class $v$. It follows from the description (5.2) that $\Psi_{V}$ factorizes through the quotient

$$
\Psi_{V}: \operatorname{Sym}^{3} \mathcal{V} \longrightarrow \mathbb{C}
$$

where $\mathcal{V}:=H^{0}(\omega) / V$. We also denote by $\Psi_{V} \subset \mathbb{P V}$ its associated cubic hypersurface.

A 3-plane $W \supset V$ determines a nonzero vector $w$ in the quotient $\mathcal{V}=$ $H^{0}(\omega) / V$ and a general $w$ determines an extension (4.2) - recall that $W^{*} \cong$ $H^{0}(E)$. Hence we obtain an injective linear map $\mathcal{V} \hookrightarrow H^{1}\left(\omega^{-1}\right), w \mapsto e$, which we compose with (4.4)

$$
\Phi: \mathcal{V} \hookrightarrow H^{1}\left(\omega^{-1}\right)=H^{0}\left(\omega^{2}\right)^{*} \hookrightarrow \operatorname{Sym}^{2} H^{0}(\omega)^{*}, \quad w \mapsto e \mapsto \cup e
$$

Since $V \subset \operatorname{ker}(\cup e)$, we note that $\operatorname{im} \Phi \subset \operatorname{Sym}^{2} \mathcal{V}^{*}$.
We now can state the main result of this section.

Proposition 5.1. The linear map $\Phi: \mathcal{V} \rightarrow \operatorname{Sym}^{2} \mathcal{V}^{*}$ coincides with the polar map of the cubic form $\Psi_{V}$, i.e.,

$$
\forall w \in \mathcal{V}, \quad \Phi(w)=P_{w}\left(\Psi_{V}\right)
$$

Proof. This is straightforwardly read from the diagram obtained by relating the exact sequences (5.1) and (2.1) via the inclusion $V \subset W$. We leave the details to the reader.

We also observe that, by definition of the Hessian hypersurface (see e.g. [DK] Section 3), we have an equality among degree $g-2$ hypersurfaces of $\mathbb{P} \mathcal{V}=\mathbb{P}^{g-3}$

$$
\begin{equation*}
\operatorname{Hess}\left(\Psi_{V}\right)=\mathcal{D} \cap \mathbb{P} \mathcal{V} \tag{5.3}
\end{equation*}
$$

where we use the inclusion $\mathbb{P V} \subset \operatorname{Gr}\left(3, H^{0}(\omega)\right)$.
Remark 5.2. We recall (see [DK] (5.2.1)) that the Hessian and Steinerian of a cubic hypersurface coincide and that the Steinerian map is a rational involution $i$. In the case of the cubic $\Psi_{V}$, the involution

$$
i: \operatorname{Hess}\left(\Psi_{V}\right) \longrightarrow \operatorname{Hess}\left(\Psi_{V}\right)
$$

corresponds to the involution of [BV] Propositions 1.18 and 1.19 , i.e., $\forall w \in$ $\mathcal{D} \cap \mathbb{P V}$, the bundles $E_{w}$ and $E_{i(w)}$ are related by the exact sequence

$$
0 \longrightarrow E_{i(w)}^{*} \longrightarrow \mathcal{O}_{C} \otimes H^{0}\left(E_{w}\right) \xrightarrow{e v} E_{w} \longrightarrow 0
$$

Since we will not use that result, we leave its proof to the reader.

Remark 5.3. The construction which associates to a base-point-free pencil $V \subset H^{0}(\omega)$ the extension class $v \in\left|\omega^{3}\right|^{*}$ induces a rational map

$$
\operatorname{Gr}\left(2, H^{0}(\omega)\right) \longrightarrow\left|\omega^{3}\right|^{*}, \quad V \longmapsto v
$$

It is worthwhile to investigate the possible relations between that map and the Wahl map

$$
\operatorname{Gr}\left(2, H^{0}(\omega)\right) \longrightarrow\left|\omega^{3}\right|, \quad V=\langle s, t\rangle \longmapsto t^{\otimes 2} d(s / t)
$$

## 6. - Base loci of $\left|F_{3}\right|$ and $\left|F_{4}\right|$

Let us denote by $\left|F_{3}\right| \subset|I(3)|$ and $\left|F_{4}\right| \subset|I(4)|$ the linear subsystems spanned by the image of the rational maps $\mathbf{F}_{3}$ and $\mathbf{F}_{4}$ respectively. Then we have the following

Theorem 6.1. The base loci of $\left|F_{3}\right|$ and $\left|F_{4}\right|$ coincide with the canonical curve $C \subset|\omega|^{*}$.

Proof. Let $b \in \mathrm{Bs}\left|F_{3}\right|$ and let us suppose that $b \notin C$. We consider a base-point-free pencil $V \subset H_{b}$. With the notation of section 5 , we introduce the rational map

$$
r_{b}: \mathbb{P V}-\mathbb{P} \mathcal{V}, \quad w \mapsto r_{b}(w)=w^{\prime}, \quad \text { with } \quad \tilde{\Psi}_{V}\left(w, w^{\prime}, \cdot\right)=b
$$

where $\tilde{\Psi}_{V}$ is the symmetric trilinear form of $\Psi_{V}$. We note (Proposition 4.2) that, for $w \notin \mathbb{P}\left(H_{b} / V\right)$, the element $r_{b}(w)$ is collinear with the nonzero element $f_{0} \wedge f_{1} \bmod V$ and that $r_{b}$ is defined away from the hypersurface $\operatorname{Hess}\left(\Psi_{V}\right)$, which we assume to be nonzero. Since $b \in \mathrm{Bs}\left|F_{3}\right|$ we obtain by Proposition 4.4 that

$$
r_{b}(w)=\left(\bigcap_{x \in W^{\perp}} H_{x}\right) \bmod V=W \bmod V=w
$$

Hence $r_{b}$ is the identity map (away from $\operatorname{Hess}\left(\Psi_{V}\right)$ ). This implies that $\tilde{\Psi}_{V}(w, w, \cdot)=b$ for any $w \in \mathbb{P V}$, hence $\Psi_{V}=x_{0}^{3}$, where $x_{0}$ is the equation of the hyperplane $\mathbb{P}\left(H_{b} / V\right) \subset \mathbb{P V}$. This in turn implies that $\operatorname{Hess}\left(\Psi_{V}\right)=0$, i.e., $\mathbb{P} \mathcal{V} \subset \mathcal{D}$. Since for a general $[W] \in \operatorname{Gr}\left(3, H^{0}(\omega)\right)$ the pencil $V=W \cap H_{b}$ is base-point-free, we obtain that a general [ $W$ ] lies on the divisor $\mathcal{D}$, which is a contradiction.

As for $\left|F_{4}\right|$, we recall that the fact $\mathrm{Bs}\left|F_{4}\right|=C$ follows from [We]. Alternatively, it can also be deduced by noticing (see Proposition 2.3) that $\mathrm{Bs}\left|F_{4}\right| \subset \mathrm{Bs}|I(2)|$. Hence, if $C$ is not trigonal nor a plane quintic, we are done. In the other cases, the result can be deduced from Proposition 4.3 we leave the details to the reader.

## 7. - Open questions

## 7.1. - Dimensions

The projective dimensions of the linear systems $\left|F_{3}\right|$ and $\left|F_{4}\right|$ are not known for general $g$. The known values of $\operatorname{dim}\left|F_{4}\right|$ for a general curve $C$ are given as follows (see [PP]).

| $g$ | 4 | 5 | 6 | 7 |
| :---: | ---: | ---: | ---: | ---: |
| $\operatorname{dim}\left\|F_{4}\right\|$ | 4 | 15 | 40 | 88 |

The examples of [PP] section 6 show that $\operatorname{dim}\left|F_{4}\right|$ depends on the gonality of $C$. Moreover it can be shown that $\left|F_{4}\right| \neq|I(4)|$.

## 7.2. - Prym-canonical spaces and symplectic bundles

The construction of the quartic hypersurfaces $F_{W}$ admits various analogues and generalizations, which we briefly outline.
(1) Let $P_{\alpha}:=\operatorname{Prym}\left(C_{\alpha} / C\right)$ denote the Prym variety of the étale double cover $C_{\alpha} \rightarrow C$ associated to the nonzero 2-torsion point $\alpha \in J C$. Given a general 3-plane $Z \subset H^{0}(C, \omega \alpha)$, we associate the rank-2 vector bundle $E_{Z}$ defined by

$$
0 \longrightarrow E_{Z}^{*} \longrightarrow \mathcal{O}_{C} \otimes Z \xrightarrow{e v} \omega \alpha \longrightarrow 0 .
$$

By [IP] Proposition 4.1 we can associate to $E_{Z}$ the divisor $\Delta\left(E_{Z}\right) \in|2 \Xi|$, where $\Xi$ is a symmetric principal polarization on $P_{\alpha}$. Its projectivized tangent cone at the origin $0 \in P_{\alpha}$ is a quartic hypersurface $F_{Z}$ in the Prym-canonical space $\mathbb{P} T_{0} P_{\alpha} \cong|\omega \alpha|^{*}$. Kempf's obstruction theory equally applies to the quartics $F_{Z}$. We note that $F_{Z}$ contains the Prym-canonical curve $i_{\omega \alpha}(C) \subset|\omega \alpha|^{*}$.
(2) Let $W$ be a vector space of dimension $2 n+1$, for $n \geq 1$. We consider a general linear map

$$
\Phi: \Lambda^{2} W^{*} \longrightarrow H^{0}(C, \omega)
$$

By taking the $n$-th symmetric power $\operatorname{Sym}^{n} \Phi$ and using the canonical maps $\operatorname{Sym}^{n}\left(\Lambda^{2} W^{*}\right) \rightarrow \Lambda^{2 n} W^{*} \cong W$ and $\operatorname{Sym}^{n} H^{0}(\omega) \rightarrow H^{0}\left(\omega^{\otimes n}\right)$, we obtain a linear map

$$
\alpha: W \longrightarrow H^{0}\left(\omega^{\otimes n}\right)
$$

which we assume to be injective. We then define the rank $2 n$ vector bundle $E_{\Phi}$ by

$$
0 \longrightarrow E_{\Phi}^{*} \longrightarrow \mathcal{O}_{C} \otimes W \xrightarrow{e v} \omega^{\otimes n} \longrightarrow 0
$$

The bundle $E_{\Phi}$ carries an $\omega$-valued symplectic form and the projectivized tangent cone at $\mathcal{O} \in J C$ to the divisor $D\left(E_{\Phi}\right)$ is a hypersurface $F_{\Phi}$ in $|\omega|^{*}$ of degree $2 n+2$. Moreover $F_{\Phi} \in|I(2 n+2)|$.
