## PREFACE

These notes originated at the Second Algebraic Geometry Summer Seminar held at the University of Utah during August 1991. The seminar was the continuation of the First Summer Seminar held in 1987 whose notes appeared in [CKM88].

The aim of the First Summer Seminar was to give an introduction to three dimensional birational geometry, especially to Mori's Program (also called the Minimal Model Program). We are very happy to note that in the last few years this program has become much better known among algebraic geometers. This was reflected in the number of participants. In 1987 there were 16 participants for an introductory seminar; in 1991 there were 30 for a more advanced one.

Because of these changes, instead of starting at the beginning, the Second Summer Seminar concentrated on reviewing recent developments in higher dimensional birational geometry. We surveyed two of the most important recent directions.

The first topic was the existence of flips in dimension three, the final step in the three dimensional Minimal Model Program. In surface theory it is well known that repeated contraction of -1 -curves yields a minimal surface. Similarly, starting with a threefold $X$, Mori's Program produces another threefold $X^{\prime}$, birational to $X$, which can reasonably be called minimal in analogy with the surface case. The required operations are however more complicated. One of them is called flip.

The existence of flips was first proved by [Mori88]. Recently a very different approach to a more general type of flipping problem (still in dimension three) was found by [Shokurov91]. We owe special thanks to Miles Reid who prepared an English translation of [Shokurov91] in a very short time. Shokurov's article contains many new ideas, but unfortunately it is very difficult to understand. Numerous parts required a truly joint effort of the participants and some details were understood only after several discussions with the author. Eventually we discovered an error in [ibid, 8.3]. Unfortunately, there was no opportunity to reconvene the seminar and study the new version [Shokurov92].

The first part of the notes (Chapters 4-8) presents a new proof of log flips using [Mori88]. The third part (Chapters 16-21) presents a reworked version of [Shokurov91, 1-7].

The second topic (Chapters 9-15) is the Abundance Conjecture proposed in [Reid83]. It is a natural continuation of Mori's Program. Starting with the threefold $X^{\prime}$ produced above, the conjecture states that a suitable multiple of the canonical class determines a base point free linear system (unless all such are empty). The proof of this result was completed in the series of articles [Kawamata84,85,91b; Miyaoka87a,b,88a,b]. Again we succeeded in simplifying several of the steps and generalizing many intermediate results.

A more detailed explanation of the results and an outline of the proofs is given in Chapter 1.

Acknowledgement. We are very grateful to S . Mori for his attention and help during and after the conference. He pointed out several mistakes in preliminary versions of the notes.

Many errors and inaccuracies were pointed out to us by S. Kovács and E. Szabó. We received long lists of comments, corrections and improvements from M. Reid and from V. V. Shokurov. They helped to improve these notes considerably.

The seminar was made possible by a generous grant from the University of Utah to S. Mori.

These notes were typeset by $\mathcal{A} \mathcal{M} \mathcal{S}$ - $\mathrm{T}_{\mathrm{E}} \mathrm{X}$, the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ macro system of the Americal Mathematical Society.

## PREREQUISITES

In writing these notes we tried to keep the prerequisites to the minimum. The reader is assumed to have a basic general knowledge of algebraic geometry. Some familiarity with higher dimensional techniques is necessary. We tried to rely only on Chapters 1-13 of [CKM88]. There are however two topics not adequately covered in [CKM88].

1. In [CKM88] the Cone Theorem and related results are proved only for the canonical divisor $K_{X}$ instead of an arbitrary log terminal divisor $K_{X}+\Delta$. The proofs in the more general log terminal case are essentially the same as the proofs given in [CKM88]. A reader who understands Chapters 9-13 of [CKM88] should have no problem with the more general log versions. However we usually refer to [KMM87] where the precise results are stated and proved.
2. [CKM88, Chapter 6] collects the most important results on terminal and canonical singularities in dimension three, mostly without proofs. The reader who is happy to accept these results does not need to know more. For those who want proofs, the list of prerequisites gets longer. The survey article [Reid87] presents a very readable and elementary overview with proofs. Unfortunately even [Reid87] relies on detailed properties of elliptic Gorenstein surface singularities [Laufer77; Reid75] which are by no means basic. We could not offer any significant improvements; thus there was no reason to reproduce the results.
3. The first proof of the existence of $\log$ flips (Chapters 4-8) uses the very difficult results of [Mori88]. We need however only the statements and none of the techniques.
4. In Chapter 9 we discuss the abundance problem only for regular threefolds. The irregular case was solved earlier using the ideas of Iitaka's program which are not related to the methods discussed here.

No other result from higher dimensional birational geometry is used without proof.

We also need some other results which are not part of basic algebraic geometry.

Naturally we need Hironaka's resolution of singularities.
Simultaneous resolution of flat deformations of Du Val singularities (= rational double points) is an important result [Brieskorn71] which is not treated
in textbooks.
In Chapters 9-10 we use several properties of stable vector bundles. Also in Chapter 9 we need some properties of foliations in positive characteristic. In all cases we state the results we use and give precise references.

Finally there are occasional uses of a few other topics: mixed Hodge structures, Lefschetz type theorems, relative duality and the existence of the Hilbert scheme.

# 1. LOG FLIPS AND ABUNDANCE: AN OVERVIEW 

JÁnos Kollár

The aim of these notes is to present two of the most important recent directions of three dimensional algebraic geometry. We generalize the following two theorems from surfaces to threefolds. (For the surface case, see for example, [BPV84,VI.1.1,V.12.1,VII.5.2].):
1.1 Theorem. Let $X$ be a smooth projective surface. Then there is a birational morphism $X \rightarrow X^{\prime}$ to another smooth projective surface $X^{\prime}$, where $X^{\prime}$ satisfies exactly one of the following conditions:
(1.1.1) $K_{X^{\prime}}$ is nef, i.e. $C \cdot K_{X^{\prime}} \geq 0$ for every curve $C \subset X^{\prime}$;
(1.1.2) $X^{\prime}$ is $\mathbb{P}^{1}$-bundle over a smooth curve $D$;
(1.1.3) $X^{\prime} \cong \mathbb{P}^{2}$.
1.2 Theorem. Let $Y$ be a smooth projective surface. Assume that $K_{Y}$ is nef. Then $\left|m K_{Y}\right|$ is base point free for some $m>0$.

The approach to the higher dimensional version of (1.1) is called Mori's program or the Minimal Model Program, initiated in [Mori82]. (See [KMM87; Kollár90; Kollár91] for introductions.) Its general features have been well understood for a few years and they were presented in [CKM88,1-13] in a fairly elementary way. The major remaining open problem was to prove the existence of flips. This was finally done in [Mori88]. Recently a new proof (of a more general result) was given in [Shokurov91]; we present two proofs of this result. The first one (Chapters 4-8) is short, but relies on [Mori88]. The approach of [Shokurov91] is presented in Chapters 16-22.

The higher dimensional version of (1.2) is called the Abundance Conjecture [Reid83, 4.6]. In dimension three it is now a theorem; proved in the second part (Chapters 9-15).

Before giving a detailed outline of the three dimensional proofs, I give a very short sketch of the surface case and discuss the new features of the three dimensional case.

The proof of (1.1) is relatively easy (cf. [BPV84,III.4.1,VI.2.4], [CKM88,3]). One proves that if $X$ does not satisfy any of the conditions (1.1.1-3) then it

## J. KOLLÁR

contains a smooth rational curve $C \subset X$ such that $C \cdot K_{X}=-1 . C$ can be contracted by a morphism $p: X \rightarrow X_{1}$ and $X_{1}$ is again smooth. We repeat this as many times as necessary. At every step the second Betti number drops by one, and therefore eventually the procedure must stop.

In dimension three, life is more complicated. The very first step $X \rightarrow X_{1}$ was analyzed in [Mori82]. He showed that in some cases $X_{1}$ is necessarily singular. At first sight this seems a major trouble; however, the techniques to handle the singularities that occur have been worked out. The big problem is that in subsequent steps we may arrive at a situation when the contraction forced upon us by the program is of the following type:

Small Extremal Contraction. $f: X \rightarrow Z$ is a proper birational morphism between threefolds such that the exceptional set of $f$ is a curve $C \subset X$ and $K_{X}$ is negative on $C$.

In this case $Z$ has "very bad" singularities. This makes it necessary to find a new type of birational transformation, the flip.

Flips. Let $f:(C \subset X) \rightarrow(P \in Z)$ be a proper birational morphism such that $f:(X-C) \rightarrow(Z-P)$ is an isomorphism. Assume that $K_{X}$ is negative on $C$. The flip of $f$ is a proper birational morphism $f^{+}:\left(C^{+} \subset X^{+}\right) \rightarrow(P \in Z)$ such that $f^{+}: X^{+}-C^{+} \rightarrow Z-P$ is an isomorphism, and $K_{X^{+}}$is positive on $C^{+}$. This gives the following diagram:

(Frequently the birational map $\phi=\left(f^{+}\right)^{-1} \circ f: X \rightarrow X^{+}$is also called the flip.)

Informally, we take $C$ out of $X$ and replace it with another curve $C^{+}$. The main point is that the canonical class becomes positive near $C^{+}$. Aside from the sign restriction on $K$, the flip might seem to be a symmetric operation; however, the negativity of $K_{X} \cdot C$ is crucial.

The existence of flips was the main open problem of three dimensional birational geometry for six years, until it was finally settled by [Mori88].

The first and third parts of these notes present a generalized version of flips. We look at perturbations of $K_{X}$ of the form $K_{X}+\sum b_{i} B_{i}$ where the $B_{i}$ are effective and $0 \leq b_{i} \leq 1$. There are further strong restrictions on the singularities of $X$ and of the $B_{i}$ which are not important for the general picture. Instead of requiring that $K_{X} \cdot C$ be negative, we require that $\left(K_{X}+\right.$
$\left.\sum b_{i} B_{i}\right) \cdot C$ be negative. This generalization gives us considerable flexibility in certain problems which is crucial in many applications.

The proofs of [Mori88] and of [Shokurov91] proceed along very different lines. The technical heart of [Mori88] is a method to understand the structure of $X$ along $C$. Once we understand the structure sufficiently well, it is not too hard to construct the flip. This approach was further developed into a fairly complete structure theory of all possible pairs $C \subset X$ [Kollár-Mori92]. In particular, this method gives a very good description of $X^{+}$in all cases.
[Shokurov91] has a more general situation where a complete description may very well be intractable. Thus he concentrates on trying to prove the existence of flips. His method is to have various results to the effect that if certain flips exist then some more general flips also exist. There are about five main types of reductions, each applied several times. This has the consequence that we know very little about $X^{+}$.

At the end of the program we obtain the following theorems. First we state the original version of [Mori88], then the generalized version of [Shokurov91].
1.3 Theorem. (Existence of minimal models) Let $X$ be a smooth projective threefold. Then there is a birational map $X \rightarrow X^{\prime}$ to another projective threefold $X^{\prime}$ (with terminal singularities), where $X^{\prime}$ satisfies exactly one of the following conditions:
(1.3.1) $K_{X^{\prime}}$ is nef, i.e. $C \cdot K_{X^{\prime}} \geq 0$ for every curve $C \subset X^{\prime}$;
(1.3.2) There is a morphism $p: X^{\prime} \rightarrow Z^{\prime}$ onto a lower dimensional variety $Z^{\prime}$ such that $K_{X^{\prime}}$ is negative on the fibers of $f$.
1.4 Theorem. (Existence of log minimal models) Let $X$ be a smooth projective threefold. Let $D=\sum d_{i} D_{i}$ where the $D_{i}$ are different irreducible divisors, Supp $D$ has only normal crossings and $0 \leq d_{i} \leq 1$.

Then there is a birational map $\phi: X \rightarrow X^{\prime}$ to another projective threefold $X^{\prime}$ such that $\left(X^{\prime}, D^{\prime}=\phi_{*}(D)\right)$ is log terminal (see (2.13)), and $X^{\prime}$ satisfies exactly one of the following conditions:
(1.4.1) $K_{X^{\prime}}+D^{\prime}$ is nef, i.e. $C \cdot\left(K_{X^{\prime}}+D^{\prime}\right) \geq 0$ for every curve $C \subset X^{\prime}$.
(1.4.2) There is a morphism $p: X^{\prime} \rightarrow Z^{\prime}$ onto a lower dimensional variety $Z^{\prime}$ such that $K_{X^{\prime}}+D^{\prime}$ is negative on the fibers of $p$.

A lot of work has been done on the structure of $X^{\prime}$ in the second case of (1.3) and (1.4), especially when $D=\emptyset$. Some of the most important contributions are [Sarkisov81,82; Miyaoka-Mori86; Iskovskikh87; Kawamata91a; Alexeev92; Corti92]. We do not say much about this direction, except for some very special examples in Chapter 23.

The second part of these notes concerns the following generalization of (1.2) conjectured in [Reid83,4.6] and proved in a series of articles [Kawamata84,85,91b; Miyaoka87a,b,88a,b].

## J. KOLLÁR

1.5 Theorem. Let $Y$ be a projective threefold with terminal singularities such that $K_{Y}$ is nef. Then $\left|m K_{Y}\right|$ is base point free for some $m>0$.

In order to see the difficulties of the proof, we recall the main steps of the two dimensional argument. By Riemann-Roch we have
$h^{0}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right)+h^{2}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right) \geq \chi\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right)=\frac{m(m-1)}{2} K_{Y}^{2}+\chi\left(\mathcal{O}_{Y}\right)$.
If $K_{Y}^{2}>0$ then $h^{0}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right) \rightarrow \infty$, and therefore we have lots of sections. This corresponds to the case when $\left|m K_{Y}\right|$ gives a birational morphism for $m \gg 1$.

Thus assume that $K_{Y}^{2}=0$. Here we are in trouble since we only get $h^{0}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right) \geq \chi\left(\mathcal{O}_{Y}\right)-1$. In the elliptic surface case we have to prove that both $h^{0}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right)$ and $h^{1}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right)$ go to infinity, but they cancel each other out.

We have two different cases.
Irregular surfaces. We use the Albanese morphism $Y \rightarrow \mathrm{Alb}(Y)$ to get some information. Subvarieties of Abelian varieties are rather special, hence we can expect that analyzing the morphism gives us all necessary information. This part can be generalized rather successfully to higher dimensions, and it leads to several general conjectures of Iitaka, most of which were proved by Ueno, Fujita, Viehweg, Kawamata, Kollár and others. See [Mori87] for a survey.

Regular surfaces. In this case $\chi\left(\mathcal{O}_{Y}\right) \geq 1$,

$$
h^{0}\left(\mathcal{O}\left(2 K_{Y}\right)\right)+h^{0}\left(\mathcal{O}\left(-K_{Y}\right)\right) \geq 1
$$

Therefore we can find an effective divisor $D \in\left|2 K_{Y}\right|$. If we expect that $2 K_{Y}$ is trivial (i.e., $K 3$ or Enriques surfaces) then $D=\emptyset$ and we are done. Otherwise we expect that $Y$ is an elliptic surface and $D$ is supported on fibers of the elliptic fibration. We need to show that (some multiple of) $D$ moves in a pencil. There are two problems here. First, $D$ can be very singular. Second, it is not at all obvious that $D$ moves, even if it is smooth. This part is rather delicate even for surfaces.

The three dimensional version proceeds along the same main lines. The irregular case has been treated earlier by the methods of the Iitaka conjectures mentioned above [Viehweg80]. We do not deal with this part. Thus we are left with the regular case.

First we look at Riemann-Roch. Because of the singularities, the precise form is not easy to work out. It was done by Barlow-Fletcher-Reid
[Reid87,10.3]:

$$
\begin{aligned}
h^{0}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right)+h^{2}\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right) \geq & \chi\left(\mathcal{O}_{Y}\left(m K_{Y}\right)\right) \\
= & \frac{m(m-1)(2 m-1)}{6} K_{Y}^{3}+\frac{m}{12} K_{Y} \cdot c_{2}(Y) \\
& +\chi\left(\mathcal{O}_{Y}\right)+l(Y, m)
\end{aligned}
$$

where $l(Y, m)$ is a periodic function of $m$, depending only on the singularities of $Y$.

If $K_{Y}^{3}>0$ then general methods of the Base Point Free Theorem give the result (see, e.g., [CKM88,9.3]). The next main step, due to [Miyaoka87a,b], is to show that $K_{Y} \cdot c_{2}(Y) \geq 0$. After further difficulties, we can at least show that if $K_{Y}$ is nef then $\left|m K_{Y}\right| \neq \emptyset$ for some $m>0$ [Miyaoka88a].

A further step was taken by [Miyaoka88b] who settled the problem completely in the case when we expect $Y$ to be a pencil of K3-surfaces. The arguments are analogous to the elliptic surface case, but technically much more involved.

The elliptic threefold case was first studied by [Matsuki90], using the ideas of [Miyaoka88b]. He was able to achieve only partial results. Finally, this method was further developed in [Kawamata91b]. He improved Matsuki's argument at a decisive point. In general, one needs to deal with the possibility that $D \in\left|m K_{Y}\right|$ is badly singular. Kawamata considers a log minimal model for $K+\operatorname{red} D$. While we get more complicated threefold singularities, the resulting member of $|m K|$ becomes much better, which is crucial.

Before we give a detailed outline of the proofs, we need to discuss a little about the relevant singularities.

## Singularities

Singularities enter into the program already at the first step [Mori82] and [Reid80,83], and understanding them is an indispensable initial part of three dimensional birational geometry. See [Reid87] for a general introduction.

The following observations lead to the correct classes of singularities.
(1.6.1). Our main interest is in studying the canonical class $K_{X}$ and in being able to compute its intersection numbers with curves. Thus we need $K_{X}$ to be Cartier or at least $\mathbb{Q}$-Cartier (i.e., a multiple of $K_{X}$ is Cartier). Frequently we may even restrict ourselves to the case when every Weil divisor is $\mathbb{Q}$-Cartier. (1.6.2). Let $X$ be a normal variety such that $K_{X}$ is $\mathbb{Q}$-Cartier. Let $f: Y \rightarrow X$ be a proper birational morphism. We can write

$$
K_{Y} \equiv f^{*} K_{X}+\sum a(E, X) E
$$

where $E \subset Y$ are exceptional divisors, $a(E, X) \in \mathbb{Q}$ and $\equiv$ denotes numerical equivalence.
$a(E, X)$ is called the discrepancy of $E$ with respect to $X . f(E) \subset X$ is called the center of $E$ on $X$ and is denoted by $\operatorname{Center}_{X}(E)$. A divisor $E$ is called exceptional if $\operatorname{dim} \operatorname{Center}_{X}(E) \leq \operatorname{dim} X-2$.

If $f^{\prime}: Y^{\prime} \rightarrow X$ is another proper birational morphism and $E^{\prime} \subset Y^{\prime}$ is the birational transform (2.4.1) of $E$ on $Y^{\prime}$ then $a(E, X)=a\left(E^{\prime}, X\right)$ and $\operatorname{Center}_{X}(E)=\operatorname{Center}_{X}\left(E^{\prime}\right)$. In this sense $a(E, X)$ and $\operatorname{Center}_{X}(E)$ depend only on the divisor $E$ but not on $Y$. This is the reason why $Y$ is suppressed in the notation. A more invariant description is obtained by considering the rank one discrete valuation of the function field $\mathbb{C}(X)$ corresponding to a divisor. Thus we obtain a function

$$
a(, X):\{\text { divisors of } \mathbb{C}(X) \text { with nonempty center on } X\} \rightarrow \mathbb{Q} .
$$

(If $X$ is proper then every divisor has a nonempty center.)
(1.6.3) It turns out to be very natural to measure the singularities of a variety $X$ by the behavior of the discrepancy function. The most important measure is given by
$\operatorname{discrep}(X)=\inf _{E}\left\{a(E, X) \mid E\right.$ exceptional, $\left.\operatorname{Center}_{X}(E) \neq \emptyset\right\} \in \mathbb{R} \cup\{-\infty\}$.
The following is clear by considering the blow up of a codimension two subvariety:

### 1.7 Claim. If $X$ is smooth then $\operatorname{discrep}(X)=1$.

This property is close to characterizing smooth varieties. The precise statement is the following.
1.8 Conjecture. Let $X$ be a normal variety such that $K_{X}$ is $\mathbb{Q}$-Cartier. Then $X$ is smooth iff

$$
a(E, X) \geq \operatorname{dim} X-\operatorname{dim}\left(\operatorname{Center}_{X}(E)\right)-1 \quad \text { for every } E .
$$

This is true if $\operatorname{dim} X \leq 3$ (cf. (17.1.2)).
For arbitrary varieties the following result limits the possibilities:
1.9 Proposition. [CKM88,6.3] Let $X$ be a normal variety such that $K_{X}$ is $\mathbb{Q}$-Cartier. Then one of the following holds:
(1.9.1) discrep $(X) \in[-1,1]$ and the inf is a minimum;
(1.9.2) $\operatorname{discrep}(X)=-\infty$.

For most singular varieties we have (1.9.2) and the first case should be considered very special. In general, the larger discrep $(X)$, the milder the singularities of $X$.

There are four classes that deserve special attention:
1.10 Definition. Let $X$ be a normal variety such that $K_{X}$ is $\mathbb{Q}$-Cartier. We say that
$X$ has $\left\{\begin{array}{l}\text { terminal } \\ \text { canonical } \\ \log \text { terminal } \\ \log \text { canonical }\end{array} \quad\right.$ singularities if discrep $(X)\left\{\begin{array}{l}>0, \\ \geq 0, \\ >-1, \\ \geq-1 .\end{array}\right.$
In dimension two these classes correspond to well-known classes of singularities:
1.11 Theorem. Let $0 \in X$ be a (germ of a) normal surface singularity over $\mathbb{C}$. Then $X$ is

```
    terminal \(\Leftrightarrow\) smooth;
canonical \(\Leftrightarrow \mathbb{C}^{2} /(\) finite subgroup of \(S L(2, \mathbb{C})\) );
\(\log\) terminal \(\Leftrightarrow \mathbb{C}^{2} /(\) finite subgroup of \(G L(2, \mathbb{C})\) );
log canonical \(\Leftrightarrow\) simple elliptic, cusp, smooth or a quotient of these
```

All of these classes occupy an important place in the theory:
(1.12.1). Terminal singularities are the smallest class in which Mori's program can work, even if we start with smooth and projective varieties.
(1.12.2). Canonical singularities are precisely those that appear on the canonical models of smooth varieties of general type. [Reid80]
(1.12.3). Log terminal singularities are precisely those that appear on the canonical models of smooth varieties of nongeneral type. [Kawamata85; Nakayama88]

Log canonical singularities appear naturally in a different context:
1.13 Conjecture. Let $X$ be a proper and normal variety such that $K_{X}$ is Q-Cartier.
(1.13.1) If $X$ has $\log$ canonical singularities then

$$
H^{i}(X, \mathbb{C}) \rightarrow H^{i}\left(X, \mathcal{O}_{X}\right) \quad \text { is surjective for every } i
$$

(1.13.2) Log canonical is the largest class where the above surjectivity holds.
(More precisely, there is a local version of the above surjectivity involving De Rham complexes [DuBois81; Steenbrink83], and this local version should characterize log canonical singularities.)

Both directions are true if $X$ has isolated singularities [Ishii85].

Next we introduce the "perturbations" of $K$ which are crucial in the sequel. Instead of concentrating on $K_{X}$ we consider pairs $(X, D)$, where $X$ is a normal variety and $D=\sum d_{i} D_{i}$ is a divisor such that $D_{i}$ distinct and $0 \leq d_{i} \leq 1$. Such a divisor is called a boundary. There are at least three reasons to consider these:
(1.14.1) Flexibility. By choosing $D$ appropriately, we are able to analyze situations when $K_{X}$ is small (e.g., $K_{X} \equiv 0$ ).
(1.14.2) Open varieties. Let $X$ be a smooth variety and let $X \subset \bar{X}$ be a compactification such that $D=\bar{X}-X$ is a divisor with normal crossings. $H^{j}\left(\bar{X}, \Omega_{\bar{X}}^{i}\right)$ are basic cohomological invariants of $\bar{X}$, but they depend on $\bar{X}$, not only on $X$. [Grothendieck66] discovered that the groups

$$
H^{j}\left(\bar{X}, \Omega_{\bar{X}}^{i}(\log D)\right)
$$

depend only on $X$, not on the completion $\bar{X}$. The simplest one is

$$
H^{0}\left(\bar{X}, \omega_{\bar{X}}(D)\right) \quad \text { or more generally } \quad H^{0}\left(\bar{X},\left(\omega_{\bar{X}}(D)\right)^{\otimes m}\right)
$$

Thus if we want to study properties that reflect the choice of $X$, it is natural to consider the divisor $K_{\bar{X}}+D$.
(1.14.3) Fiber spaces. The simplest example is Kodaira's canonical bundle formula for elliptic surfaces [BPV84,V.12.1]. Let $f: S \rightarrow C$ be a minimal elliptic surface. Let $m_{i} F_{i}=f^{*}\left(c_{i}\right)$ be the multiple fibers. Then

$$
\begin{aligned}
K_{S} & =f^{*} K_{C}+f^{*}\left(f_{*} K_{S / C}\right)+\sum\left(m_{i}-1\right) F_{i} \\
& \equiv f^{*}\left[K_{C}+\left(f_{*} K_{S / C}\right)+\sum\left(1-\frac{1}{m_{i}}\right)\left[c_{i}\right]\right] .
\end{aligned}
$$

Thus the study of $K_{S}$ can be reduced to the study of a divisor of the form $K_{C}+D$ where $D$ has rational coefficients. The same happens in general for fiber spaces $f: X \rightarrow Y$ where the general fiber has trivial canonical class.

The notion of discrepancy is again the fundamental measure of the singularities of $(X, D)$.
1.15 Definition. Let $X$ be a normal variety and $D=\sum d_{i} D_{i}$ a $\mathbb{Q}$-divisor (not necessarily effective) such that $K_{X}+D$ is $\mathbb{Q}$-Cartier. Let $f: Y \rightarrow X$ be a proper birational morphism. Then we can write

$$
K_{Y} \equiv f^{*}\left(K_{X}+D\right)+\sum a(E, X, D) E
$$

where $E \subset Y$ are distinct prime divisors and $a(E, X, D) \in \mathbb{Q}$. The right hand side is not unique because we allow nonexceptional divisors too. In order to make it unique we adopt the convention that a nonexceptional divisor $F$ appears in the sum iff $F=D_{i}$ for some $i$, and then with the coefficient $a(F, X, D)=-d_{i}$.

We frequently write $a(E, D)$ if no confusion is likely.
As explained in (1.6.2), $a(E, X, D)$ depends only on the divisor $E$ but not on $Y$. Thus we obtain a function

$$
a(, X, D):\{\text { divisors of } \mathbb{C}(X) \text { with nonempty center on } X\} \rightarrow \mathbb{Q}
$$

$a(E, X, D)$ is called the discrepancy of $E$ with respect to $(X, D)$. We define as in (1.6.3)

$$
\operatorname{discrep}(X, D)=\inf _{E}\left\{a(E, X, D) \mid E \text { is exceptional, } \operatorname{Center}_{X}(E) \neq \emptyset\right\}
$$

We also use the notation $\operatorname{logdiscrep}(X, D)=1+\operatorname{discrep}(X, D)$.
1.16 Definition. Let $X$ be a normal variety. Let $D=\sum d_{i} D_{i}$ be an effective $\mathbb{Q}$-divisor such that $K_{X}+D$ is $\mathbb{Q}$-Cartier. We say that

$$
(X, D) \text { or } K_{X}+D \quad \text { is }\left\{\begin{array} { l } 
{ \text { terminal } } \\
{ \text { canonical } } \\
{ \text { purely log terminal } } \\
{ \operatorname { l o g } \text { canonical } }
\end{array} \quad \text { if } \operatorname { d i s c r e p } ( X ) \left\{\begin{array}{l}
>0 \\
\geq 0 \\
>-1 \\
\geq-1
\end{array}\right.\right.
$$

We say that $(X, D)$ is Kawamata $\log$ terminal if $(X, D)$ is purely log terminal and $d_{i}<1$ for every $i$.
1.17 Remark. If $D=\emptyset$ then these definitions agree with (1.10). One should note that if $D \neq \emptyset$ then the terminal and canonical conditions on a log variety $(X, D)$ are not preserved under extremal contractions in general.

The divisors $K+D$ that appear in the context of (1.14.3) are Kawamata log terminal, but the divisors appearing in (1.14.2) are not. Arbitrary log canonical singularities form a too large class; for instance, they need not be rational.

Kawamata log terminal seems to be the largest class where the proofs of [CKM88,9-13] go through with only minor modifications (see [KMM87]).

Thus the need arises for a suitable class between Kawamata log terminal and $\log$ canonical. There can be two different objectives in defining such a class.
(1.18.1) Minimalist. Take the smallest class that is necessary in order for the Minimal Model Program to work starting with a pair ( $X, D$ ) where $X$ is smooth and $D$ is a boundary whose components are smooth and have normal crossings only.
(1.18.2) Maximalist. Take the largest class where all the relevant theorems still hold.

There are several proposed definitions (2.13). However, in my opinion none of them satisfies any of the above objectives fully. The lack of a good class leads to technical difficulties later.

## Description of the Chapters

We start with two introductory chapters: Chapter 2 gives the precise definitions and basic properties of log terminal threefolds and their log canonical models. Many of the results are rather technical and are used only toward the end of the notes. The reader should skip $(2.16-35)$ at the first reading and refer back only as necessary.

Chapter 3 gives the folklore classification of log canonical surface singularities ( $X, B$ ) with reduced (possibly empty) boundary $B$. This was first written down in [Kawamata88]. Here we present an elementary proof, due to Alexeev, which works in any characteristic and generalizes well to fractional coefficients.

## Log Flips I.

The aim of the first major part of the notes (Chapters 4-8) is to give our first proof of the existence and termination of log flips. This proof relies on [Mori88], but is otherwise fairly short.

Chapter 4 deals with flops and flips on threefolds with terminal singularities. First we prove the existence of flops due to [Reid83] and the termination of flops and flips. The arguments are taken from [Kawamata88, Kollár89, Matsuki91, Kawamata91c] with several improvements. The main result is the following:
1.19=4.15 Theorem. (Termination of flips for canonical 3-folds) Let $X$ be a normal three dimensional $\mathbb{Q}$-factorial variety and $D$ an effective $\mathbb{Q}$-divisor such that $(X, D)$ is canonical. Then any sequence of flips for $(X, D)$ terminates, i.e., there is no infinite sequence

$$
\begin{gathered}
\left(X_{0}, D_{0}\right) \\
\phi_{0} \searrow\left(X_{1}, D_{1}\right) \\
\swarrow \phi_{0}^{+} \phi_{1} \searrow \\
Z_{0}
\end{gathered}
$$

where $X_{i+1}=\left(X_{i}\right)^{+}$is a $K_{X_{i}}+D_{i}$-flip of $X_{i}$ and $D_{i}$ is the birational transform of $D_{0}=D$.

Chapter 5 shows that $\log$ flips exist in the special case when $(X, D)$ is terminal or canonical (4.9). This is the point where [Mori88] is used.

Chapter 6 presents the so called Backtracking Method of flipping (6.4) which is used several times to construct flips. The first two applications are the Crepant Descent Theorems (6.10-11). These are based on earlier cases worked out in [Kawamata88, Kollár89, Kawamata91c]. The main idea is the following. We want to flip $f: X \rightarrow Z$. Assume that we can find a birational morphism $h: X^{\prime} \rightarrow X$ such that $K_{X^{\prime}}=h^{*} K_{X}$. Then we are able to construct the flip of $g$ by constructing various flips on $X^{\prime}$. In many cases, $X^{\prime}$ exists and its singularities are simpler than the singularities of $X$. The main application is the following:
$1.20=6.15$ Theorem. Assume that three dimensional terminal flips exist. Let $(X, B)$ be a log terminal $\mathbb{Q}$-factorial threefold. Then log flips exist, and any sequence of them is finite.

Chapter 7 discusses the question of termination of log flips in a special case. The arguments are taken from [Shokurov91] with several improvements.

Finally, in Chapter 8 we strengthen the previous results by proving that flips exist if $(X, D)$ is $\log$ canonical (as opposed to $\log$ terminal). The techniques are independent of the previous chapters. At the end we extend the method to prove the following log canonical version of (1.5):
$1.21=8.4$ Theorem. Let $X$ be a proper threefold. Assume that $K_{X}+D$ is $\log$ canonical, nef and big. Then $m\left(K_{X}+D\right)$ is base point free for suitable $m>0$. Thus

$$
\sum_{s=0}^{\infty} H^{0}\left(X, \mathcal{O}\left(s\left(K_{X}+D\right)\right)\right) \quad \text { is finitely generated. }
$$

## Abundance

While the general abundance problem can be formulated only for minimal models, some of its most difficult aspects were originally conjectured in a form not involving the notion of minimal models. This approach is based on the following:
1.22 Definition. A variety $X^{n}$ is called uniruled if there exists a variety $Y^{n-1}$ and a dominant rational map $Y \times \mathbb{P}^{1} \rightarrow X$. (Equivalently, there is a rational curve through every point of $X$.)
1.23 Theorem. [Miyaoka-Mori86] Let $X^{\prime}$ be as in (1.3). Then
(1.23.1) If $K_{X^{\prime}}$ is nef (1.3.1) then $X^{\prime}$ is not uniruled.
(1.23.2) If $X^{\prime}$ is as in (1.3.2) then $X^{\prime}$ is uniruled.

The first important part of abundance is the following old question, which from the new point of view is a combination of (1.3) and (1.5):
1.24 Conjecture. Let $X$ be a smooth projective variety. Then $X$ satisfies exactly one of the following conditions:
(1.24.1) $X$ is uniruled; or
(1.24.2) $h^{0}\left(X, \mathcal{O}\left(m K_{X}\right)\right)>0$ for some $m>0$.

It is in this form that the first substantial result was achieved:
1.25 Theorem. [Viehweg80,Satz I] Let $X$ be a smooth projective threefold over $\mathbb{C}$. Assume that $h^{1}\left(\mathcal{O}_{X}\right)>0$. Then exactly one of the following holds:
(1.25.1) $X$ is uniruled.
(1.25.2) $X$ is birational to a smooth variety $X^{\prime}$ such that $m K_{X^{\prime}} \sim 0$ for some $m>0$.
(1.25.3) $h^{0}\left(X, \mathcal{O}\left(m K_{X}\right)\right) \geq 2$ for some $m>0$.

As already mentioned, the proof relies on the (by now) usual techniques of the Iitaka conjectures, and we do not present it. We, however, use this result to concentrate on regular threefolds only.

While (1.24) can be stated without minimal models, its proof in dimension three requires the theory of minimal models. There are two major steps. The first one is the generic semipositivity of $\Omega_{X}^{1}$ [Miyaoka87a,b,88a]. To be precise:
1.26=9.0.1 Theorem. Let $X^{n}$ be a smooth projective variety and assume that $X$ is not uniruled. Let $H$ be sufficiently ample on $X$ and let $C$ be the complete intersection of $(n-1)$ general members of $|H|$. Then $\Omega_{X}^{1} \mid C$ does not have any quotients of negative degree.

The original proof of Miyaoka is very technical and complicated. In Chapter 9 we give a simpler proof due to Shepherd-Barron.

This result implies that various Chern numbers are nonnegative (in particular $-c_{1}(X) c_{2}(X) \geq 0$, which is exactly what we need in the RiemannRoch formula. However, even if the linear term is positive, we are not done since there is no vanishing result for the $h^{2}\left(\mathcal{O}_{X}\left(m K_{X}\right)\right)$ term. In the case when $X$ is a pencil of surfaces with trivial canonical class, both $h^{0}\left(\mathcal{O}_{X}\left(m K_{X}\right)\right)$ and $h^{2}\left(\mathcal{O}_{X}\left(m K_{X}\right)\right)$ go to infinity. The way out is to observe that if $h^{2}\left(\mathcal{O}_{X}\left(m K_{X}\right)\right) \neq 0$ then we obtain a nontrivial extension

$$
0 \rightarrow \mathcal{O}_{X}\left((1-m) K_{X}\right) \rightarrow E \rightarrow \mathcal{O}_{X} \rightarrow 0 .
$$

Analyzing the stability of $E$ leads to the necessary result. This part relies on the results of [Donaldson85]. We finally achieve the first major step toward abundance.
1.27=9.0.6 Theorem. (1.24) is true in dimension three.

The next three chapters are preliminary in nature. Chapter 10 deals with the theory of Chern classes applied to $Q$-bundles. $Q$-bundles are locally the quotients of vector bundles by finite groups; one can expect that most of the relevant results go through. [Kawamata91b] sketches the analytic approach, we present an algebraic one. The Bogomolov inequality for stable $Q$-sheaves (10.11) and an improved Bogomolov-Miyaoka-Yau inєquality for $\log$ surfaces (10.14) are due to Megyesi.

Chapter 11 proves abundance for $\log$ canonical surfaces. This was settled by [Kawamata79; Sakai83; Fujita84] (in fact their results are more general). We present only those results needed in subsequent chapters. Our proofs are adapted from three dimensional methods.

For later applications we also need to consider certain nonnormal surfaces with so called semi log canonical singularities. These are considered in Chapter 12. The key results (given in section 12.3) describe some special features of normal surfaces that were used in [Shokurov91, 6.9] for different purposes. The main ideas seem to apply in all dimensions. We also prove a version of (1.13) for semi log canonical surfaces.

With these preparations behind us, the threefold case is not that hard. First we divide the problem into four parts using the following notion.
1.28 Definition. Let $L$ be a nef line bundle on a proper variety $X$. (I.e. $L \cdot C \geq 0$ for every curve $C \subset X$.) We define its numerical Kodaira dimension by

$$
\nu(L)=\max \{k \mid \underbrace{L \cdots L}_{k-\text { factors }} \text { is not zero in } H^{2 k}(X, \mathbb{Q}) \cdot\}
$$

Clearly $0 \leq \nu(L) \leq \operatorname{dim} X$.
Two of the cases are easy to dispense with:
1.29 Theorem. Let $X$ be a projective $n$-fold with terminal singularities. Assume that $K_{X}$ is nef and let $D \in\left|m K_{X}\right|$.
(1.29.1) If $\nu\left(K_{X}\right)=0$ then $D=\emptyset$ hence $m K_{X} \sim 0$.
(1.29.2) If $\nu\left(K_{X}\right)=n$ then by [CKM88,9.3], $\left|r K_{X}\right|$ is base point free for some $r>1$.

In dimension three we are left with two cases: $\nu=1,2$. The first case was treated by [Miyaoka88b], the second by [Kawamata91b], who also simplified the proof in the first case.

Let $D \in\left|m K_{X}\right|$. The argument of Kawamata starts by replacing ( $X, D$ ) with another model $\left(X^{\prime}, D^{\prime}\right)$ such that $K_{X^{\prime}}+\operatorname{red} D^{\prime}$ is $\log$ terminal. The origins of this procedure can be traced to the double projection method of G. Fano. By the results of Chapter 16, red $D^{\prime}$ is semi $\log$ canonical. In both cases we perform some further modifications to simplify the model.

Chapter 13 considers the case $\nu\left(K_{X}\right)=1$. Here we find a model ( $X^{\prime \prime}, D^{\prime \prime}$ ) such that every connected component of $D^{\prime \prime}$ is irreducible and red $D^{\prime \prime}$ is semi log canonical (13.3.1-2). The crucial property of $D^{\prime \prime}$ is that (1.13.1) holds for semi log canonical surfaces. Once this is established, the argument of [Miyaoka88b] improved by [Kawamata91b] shows that $D^{\prime \prime}$ moves in a pencil.

Chapter 14 considers the case $\nu\left(K_{X}\right)=2$. Our arguments are different from the one given in [Kawamata91b]. By choosing a suitable model ( $X^{\prime \prime}, D^{\prime \prime}$ ) a crucial Todd class computation becomes rather easy (14.3). Furthermore, we can lift sections of $\mathcal{O}\left(n K_{X^{\prime \prime}}\right) \mid D^{\prime \prime}$ to $X^{\prime \prime}$ directly. These results however only give a pencil in $\left|m K_{X}\right|$ while we expect a morphism onto a surface.

The remaining problem was settled earlier by [Kawamata85] in a general form. His argument relies on a very technical generalization of the Base Point Free Theorem. In Chapter 15 we present a shorter geometric argument, which is however probably restricted to dimension three.

Log Flips II.

In the third major part (Chapters 16-22) we return to Shokurov's proof of $\log$ flips. This approach does not use [Mori88], and our presentation is self-contained (assuming of course [CKM88]). This proof also uses (7.1). Furthermore at the present it does not yield termination of a sequence of $\log$ flips, so that (6.11) is also needed to complete this approach to prove (1.4).

Let $S \subset X$ be a Weil divisor. In Chapter 16 we define the different Diff of a divisor in a variety. Diff $_{S}(0)$ essentially measures the failure of the adjunction formula $K_{S}=\left(K_{X}+S\right) \mid S$ in the presence of singularities. [Shokurov91] considers this under some restrictive assumptions; the general case was discovered and worked out by Corti. We also classify three dimensional log terminal singularities ( $X, B$ ) where $B$ is "large".

Then we want to use the different to relate properties of $X$ to properties of $S$. This is done in Chapter 17. The main result for the present applications is the following, called "inversion of adjunction".
1.30=17.6 Theorem. Let $X$ be normal and $S \subset X$ an irreducible divisor. Let $B=\sum b_{i} B_{i}$ be an effective $\mathbb{Q}$-divisor such that $b_{i}<1$ for every $i$, and assume that $K_{X}+S+B$ is $\mathbb{Q}$-Cartier. Then $K_{X}+S+B$ is purely log terminal in a neighborhood of $S$ iff $K_{S}+\operatorname{Diff}(B)$ is Kawamata log terminal.

In [Shokurov91] this was proved in dimension three by a rather elaborate argument. The proof in Chapter 17 works in all dimensions and is fairly short.

Chapter 18 contains the first two reduction steps. (1.30) allows us to simplify the proofs of Shokurov considerably while generalizing various parts to higher dimensions. The conclusion is the following result (still restricted to dimension three):
1.31=18.9 Theorem. Assume that the flip exists for every small contraction $g:(U, K+S) \rightarrow V$ such that $S$ is reduced, irreducible and has negative intersection with $C$ (these are called special flips).

Then the flip exists for any small contraction $f:(X, K+D) \rightarrow Z$ such that $K+D$ is Kawamata log terminal.

During the proof of (1.31) we encounter one of the major discoveries of [Shokurov88,91]. Let me describe a similar phenomenon where the complete result is known. (See [Alexeev89] for a more difficult example.)

Let $D_{2}=\{\operatorname{discrep}(X) \mid X$ is a $\log$ canonical surface $\}$.
1.32 Theorem. (Shokurov, unpublished) Notation as above. Then
(1.32.1) Any increasing subsequence of $D_{2}$ is finite;
(1.32.2) The accumulation points of $D_{2}$ are exactly

$$
-1 \quad \text { and } \quad-1+\frac{1}{2},-1+\frac{1}{3},-1+\frac{1}{4}, \ldots
$$

Shokurov's observation is that similar results hold in many different contexts. See (18.16) for the precise conjectures.

Chapter 19 considers complements on surfaces. The notion of a complement is another one of the major new inventions of [Shokurov91]. The main result (19.4) says that in many situations we can replace the boundary $\sum b_{i} B_{i}$ with another divisor $\sum b_{i}^{\prime} B_{i}^{\prime}$ such that

$$
b_{i}^{\prime} \in \frac{1}{n} \mathbb{N} \text { for every } i \text {, where } n \in\{1,2,3,4,6\} .
$$

Some other important technical results are also proved.
Unfortunately the flips required in (1.31) are still very hard to construct, and we need several preparatory results, presented in Chapter 20. We prove that the flip of $f:(X, K+B) \rightarrow Z$ exists if $B$ has at least two reduced com-ponents intersecting the contracted curve $C$ (20.7). This is used repeatedly in the next two chapters.

The special flips $g:(U, K+S) \rightarrow V$ of (1.31) are studied in Chapters ${ }^{21-22}$. In this case we have $K_{S}=(K+S) \mid S$, and therefore $g \mid S: S \rightarrow S^{\prime}$ is a $K_{S}$-negative contraction. Furthermore, by the results of Chapter $16, S$
has only $\log$ terminal singularities. Thus we are in the situation of Chapter 19 and we can analyze $g$ in terms of the properties of the surface $S$. By the results of Chapter 19 mentioned above we can find a reduced divisor $B$ and an integer $n \in\{1,2,3,4,6\}$ such that

$$
C \cdot\left(K+S+\frac{1}{n} B\right)=0 \quad \text { and } \quad K+S+\frac{1}{n} B \quad \text { is } \log \text { canonical. }
$$

Different values of $n$ present different levels of difficulty for flipping. Everything is easy if $n=1$ (21.4). The cases where $n=3,4,6$ are reduced to the $n=2$ case in (21.10).

The really hard part is the $n=2$ case. This is where [Shokurov91] contains an error ([ibid,8.3] is false). A new version ([Shokurov92]) was completed in February ' 92 . In Chapter 22 we restrict ourselves to presenting the main line of the arguments. Hopefully this helps the reader to study the complete version.

Chapter 23 is independent of the rest of the notes. It reviews the proof of an old theorem of [Morin40] and [Predonzan49] saysing that complete intersections in $\mathbb{P}^{n}$ of very low degree are unirational. This was done independently by [Ramero90].

## Further Developments

Several of the participants have continued to work on the problems discussed in these notes. Alexeev proved that $\mathcal{S}_{2}$ (fano) and hence $\mathcal{S}_{3}$ (local) and $\mathcal{S}_{4}^{0}$ (local) satisfy the ascending chain condition (cf. Chapter 18). Fong, Keel, Matsuki and $\mathrm{M}^{c}$ Kernan proved several results about log abundance for threefolds. Szabó is doing some foundational work which should clarify the various different flavors of log terminal given in (2.13).

## Flowcharts

The following diagrams exhibit the logical structure of the proofs of the principal results. The arrows indicate only the main lines of the arguments. There are many other occasional references to other parts.

## Abundance for Threefolds

$m$ stands for a sufficiently large and divisible natural number.
If $K$ is nef then $\nu=\nu(X)$ is defined in (1.28).
(For threefolds we have four cases: $\nu \in\{0,1,2,3\}$.)

Log Flips II

# 2. LOG CANONICAL MODELS 

Antonella Grassi and János Kollár

In the following we consider normal algebraic schemes or normal complex analytic spaces. All the propositions are stated in terms of the algebraic case, although the proofs work for the analytic case with minor modifications.

## Basic Definitions

### 2.1 Definition.

(2.1.1) $f: Y \rightarrow X$ denotes a map; $f: Y \rightarrow X$ a morphism, that is, a map everywhere defined. We try to be very systematic about using dash arrows for maps and solid arrows for morphisms.
(2.1.2) A modification $f: Y \rightarrow X$ is a birational map.
(2.1.3) A proper morphism $f: Y \rightarrow X$ is a contraction if $f_{*} \mathcal{O}_{Y}=\mathcal{O}_{X}$.
(2.1.4) Let $f: Y \rightarrow X$ be a contraction with $\operatorname{dim} Y=\operatorname{dim} X . f$ is a birational contraction (or blow down) if $X$ is viewed as constructed from $Y$; extraction (or blow up) if $Y$ is viewed as constructed from $X$.
(2.1.5) A modification of a proper morphism $f: X \rightarrow Z$ into a proper morphism $g: Y \rightarrow Z$ is a commutative diagram

where $\phi: X \rightarrow Y$ is a modification.
(2.1.6) A birational contraction is small if it is an isomorphism in codimension one. Equivalently, the exceptional set has codimension $\geq 2$. (The literature is rather inconsistent about the definiton of small morphism. All definitions that we know of agree in dimension three but not in higher dimensions.)
2.2 Definition. In the following $X$ is an $n$-dimensional normal variety:
S. M. F.
(2.2.1) $D=\sum d_{i} D_{i}$ with $D_{i}$ distinct prime Weil divisors, $d_{i} \in \mathbb{R}($ or $\in \mathbb{Q})$ is called an $\mathbb{R}$-divisor ( $\mathbb{Q}$-divisor).
(2.2.2) An $\mathbb{R}$ (or $\mathbb{Q}$ )-Cartier divisor $D$ is an $\mathbb{R}$ (or $\mathbb{Q}$ )-linear combination of Cartier divisors which need not to be irreducible or reduced. The index of $D$ is the smallest natural number $m$ such that $m D$ is Cartier. The index of $X$ is the index of $K_{X}$ (if it makes sense).
(2.2.3) Let $D=\sum d_{i} D_{i}$ be an $\mathbb{R}$-divisor as in (2.2.1). Set

$$
\operatorname{Supp} D=\cup\left\{\operatorname{Supp} D_{i} \text { such that } d_{i} \neq 0\right\} .
$$

(2.2.4) An $\mathbb{R}$-divisor as in (2.2.1) is a subboundary if $d_{i} \leq 1$ for all $i$ and a boundary if $0 \leq d_{i} \leq 1$ for all $i$.
(2.2.5) For $r \in \mathbb{R}$ let $\llcorner r\lrcorner=\max \{t \in \mathbb{Z}$ such that $t \leq r\}$ and $\ulcorner r\urcorner=-\llcorner-r\lrcorner$. (These are pronounced round down resp. round up.) Let $\{r\}=r-\llcorner r\lrcorner$ denote the fractional part of $r$.
(2.2.6) Assume that $D=\sum d_{i} D_{i}$ such that all the $D_{i}$ 's are distinct. Let $\llcorner D\lrcorner=\sum\left\llcorner d_{i}\right\lrcorner D_{i}$ and $\{D\}=\sum\left\{d_{i}\right\} D_{i}$. If $D$ is a boundary, $\llcorner D\lrcorner$ is the reduced part of $D ;\{D\}$ is the fractional part of $D$.

Warning: If $D$ is $\mathbb{Q}$-linearly equivalent to $D^{\prime}$, it does not follow that $\llcorner D\lrcorner$ is linearly equivalent to $\left\llcorner D^{\prime}\right\lrcorner$.
2.3 Definition. Let ( $X, D_{X}$ ) be a normal variety $X$ together with a boundary $D_{X} .\left(X, D_{X}\right)$ is a called a $\log$ variety with $\log$ canonical divisor $K_{X}+D_{X}$. If there is no danger of confusion we will denote this simply by $(X, D)$.

We think of $K_{X}+D_{X}$ as a mixed object: $K_{X}$ is a linear equivalence class, while $D_{X}$ is a fixed Weil divisor.

### 2.4 Definition.

(2.4.1) Let $f: X \rightarrow Y$ be a map which is a morphism in codimension 1 and let $D$ be a Weil divisor on $X$. We denote the image of $D$ as Weil divisor by $f_{*}(D)$. This extends by linearity to the set of all $\mathbb{R}$-Weil divisors. If $f$ is birational then $f_{*}(D)$ is called the birational, (or proper, or strict ) transform of $D$. This notation will frequently be used when $f=g^{-1}$, in which case the notation $g_{*}^{-1}(D)=\left(g^{-1}\right)_{*}(D)$ looks slightly unusual.
(2.4.2) A $\log$ morphism $f:\left(Y, D_{Y}\right) \rightarrow\left(X, D_{X}\right)$ is a morphism $f: Y \rightarrow X$ such that $f_{*}\left(D_{Y}\right) \subset D_{X}$.
2.5 Definition-Proposition. (cf. (1.15))
(2.5.1) Let $K_{X}+D_{X}$ be an $\mathbb{R}$-Cartier divisor on a normal variety $X$, and $f: Y \rightarrow X$ any extraction. Choose representatives of $K_{X}$ and $K_{Y}$ such that $f^{*}\left(K_{X}\right)$ and $K_{Y}$ coincide on the smooth locus of Y. Then

$$
K_{Y}+f_{*}^{-1}\left(D_{X}\right)=f^{*}\left(K_{X}+D_{X}\right)+\sum a\left(E_{i}, D_{X}\right) E_{i},
$$

for some real numbers $a\left(E_{i}, D_{X}\right)$; where the $\left\{E_{i}\right\}$ are the exceptional divisors.
(2.5.2) The number $a\left(E_{i}, D_{X}\right)$ does not depend on the choices made. It is called the discrepancy of $E_{i}$ with respect to $(X, D)$. When there is no danger of confusion we write $a\left(E_{i}\right)$ for $a\left(E_{i}, \emptyset\right)$.
(2.5.3) $1+a\left(E_{i}, D_{X}\right)$ is the $\log$ discrepancy (denoted by $a_{\ell}\left(E_{i}, D_{X}\right)$ ).
(2.5.4) In general we define the discrepancy of any divisor $F$ of the function field $\mathbb{C}(X)$ with center on $X$ (see also (1.6)). If $c(F)$ is the coefficient of $F$ in $D_{X}$, then we set by definition the discrepancy of $F$ to be $a\left(F, D_{X}\right)=-c(F)$, while the $\log$ discrepancy is $a_{\ell}\left(F, D_{X}\right)=1+a\left(F, D_{X}\right)=1-c(F)$.

The $\log$ discrepancy behaves better in certain formulas (cf. e.g. (20.3)).
2.6 Remark. We will sometimes need the notion of discrepancy in cases where $X$ is not normal. Instead of trying to work out the most general case, we restrict ourselves to the following special situation:
(2.6.1) $X$ is reduced, equidimensional and if $P \in X$ is a codimension one point then $P$ is either smooth or two smooth branches of $X$ intersect transversally at $P$.

If $X$ and $Y$ both satisfy (2.6.1) then we say that $f: Y \rightarrow X$ is birational if
(2.6.2) $f$ and $f^{-1}$ are isomorphisms at the generic points of $X$ and $Y$ and also at codimension one singular points of $X$ and $Y$.

In this situation one can define discrepancies exactly as in (2.5).
2.7 Definition. Let $f: X \rightarrow Y$ be any modification. Let $\left\{F_{i}\right\}$ be the exceptional divisors of $f^{-1}$.

If $K_{X}+D_{X}$ is $\mathbb{R}$-Cartier, let $\mathcal{F}=\left\{f\left(F_{i}\right)\right\}$ be a sequence of real numbers such that $1 \geq f\left(F_{i}\right) \geq \min \left\{1,-a\left(F_{i}, D_{X}\right)\right\}$. The $\mathcal{F}$-birational transform of $D_{X}$ is defined as

$$
\left(D_{X}\right)_{\mathcal{F}, Y}=f_{*}\left(D_{X}\right)+\sum f\left(F_{i}\right) F_{i}
$$

We always assume that $K_{Y}+\left(D_{X}\right)_{\mathcal{F}, Y}$ is $\mathbb{R}$-Cartier. Thus $a\left(F_{i},\left(D_{X}\right)_{\mathcal{F}, Y}\right)=$ $-f\left(F_{i}\right)$. We will frequently write $D_{\mathcal{F}, Y}$ instead of $\left(D_{X}\right)_{\mathcal{F}, Y}$. If $f\left(F_{i}\right)=1$ for every $i$ or $K_{X}+D_{X}$ is not $\mathbb{R}$-Cartier then set

$$
\left(D_{X}\right)_{Y}=f_{*}\left(D_{X}\right)+\sum F_{i} .
$$

Note that $K_{Y} \neq\left(K_{X}\right)_{Y}$.
2.8 Remark. The most important case of the $\mathcal{F}$-birational transform is given by the special choice $f\left(F_{i}\right)=1$. It turns out that in many cases the choice of $\mathcal{F}$ does not matter (cf. (2.22.1)). The freedom in our definition is sometimes convenient in intermediate steps of the proofs.
2.9 Definition. $f: Y \rightarrow X$ is a $\log$ resolution of the $\log$ variety $(X, D)$ if $Y$ is smooth and the irreducible components of $\operatorname{Supp}\left(D_{Y}\right)$ are non singular and cross normally.

It may be more natural to require only that $\operatorname{Supp}\left(D_{Y}\right)$ is locally analytically a normal crossing divisor (i.e. irreducible components are allowed to selfintersect). Our stronger requirement makes statements and proofs simpler.
2.10 Definition. Let $D_{X}$ be a boundary on a normal variety $X$.
$K_{X}+D_{X}$ is $\log$ canonical (lc) (or ( $X, D$ ) is $\log$ canonical) if $K_{X}+D_{X}$ is $\mathbb{R}$-Cartier and $a\left(E, D_{X}\right) \geq-1$ for all divisors $E$ of $\mathbb{C}(X)$ with center on $X$ (or equivalently $a_{\ell}\left(E, D_{X}\right) \geq 0$ ).

It is sufficient to check the above condition in (2.10) for one log resolution [CKM88, 6.5].

The following proposition allows us to consider only $\mathbb{Q}$-Cartier divisors:
2.11 Proposition. Let $D=\sum d_{i} D_{i}$ be an $\mathbb{R}$-Cartier divisor on $X$. Then for every $\epsilon>0$, there is a $\mathbb{Q}$-Cartier divisor $D^{\prime}=\sum d_{i}^{\prime} D_{i}$ such that
(2.11.1) $\left|d_{i}-d_{i}^{\prime}\right|<\epsilon$ for all $i$
(2.11.2) If $C$ is a curve and $D \cdot C \in \mathbb{Q}$, then $D \cdot C=D^{\prime} \cdot C$.
(2.11.3) Assume in addition that $K+D$ is $\mathbb{R}$-Cartier. Let $F$ be a divisor of $\mathbb{C}(X)$ with center on $X$. If $F$ has rational discrepancy, then $a(F, D)=a\left(F, D^{\prime}\right)$

Proof. By definition the $D_{i}$ are Cartier divisors. (2.11.2) and (2.11.3) give a system of (possibly infinitely many) rational linear equations in $\sum \mathbb{R} D_{i}$, considered as real vector space with $\mathbb{Q}$ structure. We can replace (2.11.1) by a system of rational inequalities. These systems define a nonempty rational polyhedron, whose vertices have rational coordinates. Any vertex will do as $\left\{d_{i}^{\prime}\right\}$.
2.12 Corollary. A lc $\mathbb{R}$-divisor can be replaced with a lc $\mathbb{Q}$-divisor without changing rational intersection numbers and rational discrepancies.

The following are variants of the notion of log terminal that have been introduced in the literature. Let ( $X, D$ ) be a $\log$ variety. If every coefficient in $D$ is $<1$ then the natural notion is (2.13.5), which was already defined in (1.16). If we allow some coefficients to be 1 , then the natural notion seems to be log canonical. This however seems too general for most theorems to hold. This leads to a slew of variants, four of which are introduced below. We feel that the only way to understand these is to see them used in proofs.
2.13 Definition. Let $(X, D)$ be a log variety.
(2.13.1) $(X, D)$ is $\log$ terminal (lt) if there exists a $\log$ resolution $f$ : $Y \rightarrow X$ where all the $f$-exceptional divisors have positive log discrepancies $\left(a_{\ell}\left(E_{i}, D\right)>0\right)$.
(2.13.2) $(X, D)$ is purely $\log$ terminal (plt) if the $\log$ discrepancy of every exceptional divisor of $\mathbb{C}(X)$ with center on $X$ is strictly positive.
(2.13.3) $(X, D)$ is divisorial log terminal (dlt) if there exists a log resolution such that the exceptional locus consists of divisors with strictly positive $\log$ discrepancies.
(2.13.4) $(X, D)$ is weakly Kawamata log terminal (wklt) if there exists a $\log$ resolution $f: Y \rightarrow X$ such that all the $\log$ discrepancies of the exceptional divisors with center on $X$ are positive and there exists an $f$ - anti ample divisor whose support coincides with that of the exceptional locus of $f$.
(2.13.5) ( $X, D$ ) is Kawamata log terminal (klt) if every divisor of $\mathbb{C}(X)$ having center on $X$ has positive log discrepancy. (Note that the singularities that we call klt are called "log terminal" in [KMM87, 0-2-10].)
2.14 Example. Let $X$ be a smooth surface and $D$ an irreducible curve with a node. The identity map is not a log resolution and $(X, D)$ has $\log$ canonical but not $\log$ terminal singularities.

Let $X$ be a smooth surface and $D$ a divisor consisting of 2 reduced irreducible smooth curves intersecting transversely: then $(X, D)$ is $\log$ terminal but not plt.

In both cases the exceptional divisor obtained by blowing up the singular point of $D$ has $\log$ discrepancy 0 .

The analogs of minimal models are the various versions of log minimal models (cf. (1.3-4)).

### 2.15 Definition.

(2.15.1) $g:\left(Y, D_{Y}\right) \rightarrow Z$ is a relative $\log$ minimal model or is $g \log$ terminal if $K_{Y}+D_{Y}$ is $g$-nef and $\log$ terminal. $\left(Y, D_{Y}\right)$ is a $\log$ minimal model if $K_{Y}+D_{Y}$ is nef and log terminal.
(2.15.2) $g:\left(Y, D_{Y}\right) \rightarrow Z$ is a relative log canonical model if $K_{Y}+D_{Y}$ is $g$-ample and $\log$ canonical. ( $Y, D_{Y}$ ) is a log canonical model if $K_{Y}+D_{Y}$ is ample and $\log$ canonical.
(2.15.3) $g:\left(Y, D_{Y}\right) \rightarrow Z$ is a relative weak $\log$ canonical model if $K_{Y}+D_{Y}$ is $g$-nef and $\log$ canonical.

Questions of uniqueness are discussed in (2.22).

## Basic Technical Results

We advise the reader to skip this part at the first reading and to refer back to it only as necessary.

### 2.16 Proposition.

(2.16.1) By definition $k l t \Longrightarrow p l t \Longrightarrow l t$ and $w k l t \Longrightarrow d l t \Longrightarrow l t$.
(2.16.2) Let $(X, D)$ be $\mathbb{Q}$-factorial and log terminal. Let $f: Y \rightarrow X$ be the log resolution whose existence is assumed in the definition. If $f$ is projective then $(X, D)$ is also wklt. (The assumption of projectivity might not be necessary.)
(2.16.3) $\left(X, D_{X}\right)$ is plt iff it is $l t$ and $\left\llcorner f_{*}^{-1}(D)\right\lrcorner$ is smooth.
(2.16.4) Wklt singularities are always rational.

Proof. (2.16.2) Let $f: Y \rightarrow X$ be a $\log$ resolution and $H$ an $f$-ample divisor on $Y$. Then $H+E=f^{*}\left(f_{*}(H)\right.$ ), for some effective divisor $E$ whose support coincides with that of the exceptional locus of $f . E$ is also $f$-anti ample.
(2.16.3) Consider $f: Y \rightarrow X$ and let $K_{Y}+f_{*}^{-1}(D)+\sum h_{i} H_{i} \equiv f^{*}\left(K_{X}+D\right)$ where $h_{i}=-a\left(H_{i}, D\right)<1$ for every $i$ since $(X, D)$ is lt. Let $\nu$ be any divisor of $\mathbb{C}(X)=\mathbb{C}(Y)$. Apply (4.12.1.2) with

$$
E=\left\llcorner f_{*}^{-1}(D)\right\lrcorner \quad \text { and } \quad H=\sum h_{i} H_{i}+\left\{f_{*}^{-1}(D)\right\} .
$$

By assumption $E$ is smooth, so $\operatorname{center}_{Y}(\nu)$ is contained in at most one component of $E$. Thus (4.12.1.2) implies that

$$
a_{\ell}(\nu, X, D)=a_{\ell}\left(\nu, Y, f_{*}^{-1}(D)+\sum h_{i} H_{i}\right)>-1,
$$

unless $\nu$ is one of the components of $\left\llcorner f_{*}^{-1}(D)\right\lrcorner$. Thus $(X, D)$ is plt.
(2.16.4) is proved in [KMM87, 1-3-6]; we will not need it.

The following proposition is a consequence of the definitions and of (2.11):

### 2.17 Proposition. Let $X$ be a variety.

(2.17.1) The set of boundaries $D$ for which $K+D$ is log canonical (nef, or numerically ample) is convex.
(2.17.2) The set of boundaries $D$ with support in a finite union $\cup D_{i}$ for which $K+D$ is $\log$ canonical is a rational convex polyhedron in $\sum \mathbb{R} D_{i}$.
(2.17.3) If $D^{\prime} \leq D$ are such that $K+D$ is log canonical (respectively $\log$ terminal) and $K+D^{\prime}$ is $\mathbb{R}$-Cartier, then $K+D^{\prime}$ is also log canonical (respectively log terminal). Moreover, $a\left(E_{i}, D\right) \leq a\left(E_{i}, D^{\prime}\right)$.
(2.17.4) Let $K_{X}+D=K_{X}+\sum d_{i} D_{i}$ be a log terminal divisor. Then there exists a positive number $\epsilon$ such that $K+D^{\prime}$ is log terminal for all $\mathbb{R}$-Cartier
divisors $K+D^{\prime}=K+\sum d_{i}^{\prime} D_{i}$ such that $d_{i}^{\prime} \leq \min \left\{1, d_{i}+\epsilon\right\}$. In addition if $K+D$ is plt, then $K+D^{\prime}$ is plt.
(2.17.5) If $K_{X}+D$ is plt and $K_{X}+D+D^{\prime}$ is lc, then $K+D+t D^{\prime}$ is plt for all $t \in[0,1]$.
2.18 Proposition. Let $g: Y \rightarrow Z$ be birational. Set $D_{Z}=g_{*}\left(D_{Y}\right)$ and assume that $K_{Z}+D_{Z}$ is $\mathbb{R}$-Cartier. If $g:\left(Y, D_{Y}\right) \rightarrow Z$ is a relative weak log canonical model, then

$$
K_{Y}+D_{Y} \equiv g^{*}\left(K_{Z}+D_{Z}\right)-\sum c\left(E_{i}\right) E_{i} \text { with } c\left(E_{i}\right) \geq 0, \forall i
$$

If $c\left(E_{i}\right)=0$ for every $i$ then $\left(K_{Z}, D_{Z}\right)$ is lc. Conversely, if $\left(K_{Z}, D_{Z}\right)$ is lc and $\left\llcorner D_{Y}\right\lrcorner$ contains the exceptional divisor of $g$ then $c\left(E_{i}\right)=0$ for every $i$.
Proof. This follows from (2.19), which is sometimes called "Kodaira Lemma". (Others attribute it to Zariski.)
2.19 Lemma. Let $f: Y \rightarrow X$ be a proper birational morphism. Assume that $Y$ is normal. Let $F_{i} \subset Y$ be the $f$-exceptional divisors. Let $L$ be a line bundle on $X$; let $M$ be an $f$-nef line bundle on $Y$, and let $G \subset Y$ be an effective divisor such that none of the $F_{i}$ is a component of $G$. Assume that

$$
f^{*}(L) \equiv M+G+\sum f_{i} F_{i} .
$$

Then
(2.19.1) $f_{i} \geq 0$ for every $i$.
(2.19.2) $f_{i}>0$ if $M$ is not numerically $f$-trivial on some $F_{j}$ such that $f\left(F_{i}\right)=f\left(F_{j}\right)$.
Proof. The proof is taken from [Kollár91, 5.2.5.3] with some changes. See also [Shokurov91, 1.1].

If $f$ is not projective, by the Chow Lemma there is a birational projective morphism $f^{\prime}: Y^{\prime} \rightarrow Y \rightarrow X$. If (2.19) holds for $f^{\prime}$ then it also holds for $f$. Thus assume that $f$ is projective.

Fix an $F_{i}$. By cutting with $\operatorname{dim} f\left(F_{i}\right)$ general hypersurfaces in $X$ we may assume that $f\left(F_{i}\right)$ is zero dimensional. Let $S \subset Y$ be the intersection of $\operatorname{dim} Y-2$ general hypersurfaces containing a general point of $F_{i}$. Let $E_{j}=$ $S \cap F_{j}$; this is either an irreducible curve or empty. By assumption $E_{i}$ is nonempty. $M^{\prime}=(M+G) \mid S$ is $f$-nef, thus

$$
0=f^{*} L\left|\cup E_{j} \equiv\left(M^{\prime}+\sum f_{i} F_{i}\right)\right| \cup E_{j} \equiv\left(M^{\prime}+\sum f_{j} E_{j}\right) \mid \cup E_{j},
$$

where the second sum runs only over those $E_{j}$ which are nonempty. By assumption $M$ is nef on $\cup E_{j}$, thus everything is implied by the following abstract linear algebra result (cf. [Artin62]).
2.19.3 Lemma. Let $Q($,$) be an inner product on \mathbb{R}^{n}$ with basis $\left\{E_{i}\right\}$. Assume that for every $i \neq j$ we have $Q\left(E_{i}, E_{i}\right)<0, Q\left(E_{i}, E_{j}\right) \geq 0$ and $Q$ is negative definite. Then
(2.19.3.1) Let $F=\sum \alpha_{i} E_{i}$ be such that $Q\left(F, E_{i}\right) \geq 0$. Then $\alpha_{i} \leq 0$ for every $i$ and strict inequality holds unless $F=0$.
(2.19.3.2) The matrix $\left(Q\left(E_{i}, E_{j}\right)\right)^{-1}$ has only negative entries.

Proof. Let $F=F^{+}-F^{-}$where

$$
F^{+}=\sum_{i: \alpha_{i}>0} \alpha_{i} E_{i} \quad \text { and } \quad F^{-}=\sum_{i: \alpha_{i} \leq 0}-\alpha_{i} E_{i}
$$

Assume that $F^{+} \neq 0$. Then for some $j, \alpha_{j}>0$ and $Q\left(E_{j}, F^{+}\right)<0$ since $Q$ is negative definite. Thus $Q\left(E_{j}, F\right)=Q\left(E_{j}, F^{+}\right)-Q\left(E_{j}, F^{-}\right)<0$.

Each column of the inverse satisfies the assumptions of the first part, thus they have only negative entries.
2.20 Proposition. Let $g: Y \rightarrow Z$ be a morphism:
(2.20.1) The set of boundaries $D$ for which $g$ is a relative log canonical model forms a convex subset in the set of all boundaries.
(2.20.2) The set of rational boundaries is dense in the set of all boundaries $D$ for which $g$ is a relative log canonical model.
(2.20.3) If $g: Y \rightarrow Z$ is a relative log canonical model, then $g$ is projective. Proof. This follows from (2.11) and (2.17).
2.21 Definition. Let $g: Y \rightarrow Z$ be a modification of the proper morphism $f: X \rightarrow Z$. Choose $\mathcal{F}$ as in (2.7). We obtain a diagram

(2.21.1) $g:\left(Y, D_{\mathcal{F}, Y}\right) \rightarrow Z$ is a weak log canonical model (with respect to $\mathcal{F}$ ) of $f: X \rightarrow Z$ if $g$ is a relative weak $\log$ canonical model and $a\left(G_{i}, D_{\mathcal{F}, Y}\right) \geq a\left(G_{i}, D_{X}\right)$ for all divisors $G_{i} \subset X$ that are $\phi$-exceptional. Note that by (2.7) if $F_{i}$ is a $\phi^{-1}$-exceptional divisor then $a\left(F_{i}, D_{\mathcal{F}, Y}\right) \leq$ $\max \left\{-1, a\left(F_{i}, D_{X}\right)\right\}$, thus the inequality is reversed.
(2.21.2) $g:\left(Y, D_{\mathcal{F}, Y}\right) \rightarrow Z$ is called a log terminal model of $f: X \rightarrow Z$ (with respect to $\mathcal{F}$ ) if $g$ is also a relative $\log$ minimal model (2.15.1).
(2.21.3) $g:\left(Y, D_{\mathcal{F}, Y}\right) \rightarrow Z$ is called a log canonical model of $f: X \rightarrow Z$ (with respect to $\mathcal{F}$ ) if $g$ is also a relative $\log$ canonical model (2.15.2).
(2.21.4) If $f\left(F_{i}\right)=1$ for every $i$ then we drop $\mathcal{F}$ from the notation and call $g:\left(Y, D_{Y}\right) \rightarrow Z$ a weak $\log$ canonical model etc.
2.21.5 Remark. It follows from (2.23.3) that weak $\log$ canonical models of $f$ can be described in the following more invariant way. $\phi:\left(X, D_{X}\right) \rightarrow\left(Y, D_{Y}\right)$ is a weak log canonical model of $f$ iff
(2.21.5.1) $\left(Y, D_{Y}\right) \rightarrow Z$ is a relative weak $\log$ canonical model (2.15),
(2.21.5.2) $a\left(E, D_{Y}\right) \geq a\left(E, D_{X}\right)$ for every divisor $E$ of $\mathbb{C}(X)$, and
(2.21.5.3) $a\left(E, D_{Y}\right)=\max \left\{-1, a\left(E, D_{X}\right)\right\}$ for every exceptional divisor of $g: Y \rightarrow Z$. (If $f$ is not birational, we consider every divisor $E \subset Y$ to be exceptional.)

One of our eventual main aims is to show that log terminal or log canonical models exist under various assumptions. Here we do not address the question of existence; rather, we consider basic properties of $\log$ models assuming that they exist.

### 2.22 Theorem.

(2.22.1) A log canonical model for $f: X \rightarrow Z$ is unique; in particular it does not depend on the choice of $\mathcal{F}$.
(2.22.2) If $g: Y \rightarrow Z$ is a weak $\log$ canonical model and $g^{c}: Y^{c} \rightarrow Z$ a $\log$ canonical model then there is a unique morphism $\rho: Y \rightarrow Y^{c}$ such that $g=\rho \circ g^{c}$.
(2.22.3) Let $g: Y \rightarrow Z$ be a weak $\log$ canonical model. Then a log canonical model $g^{c}: Y^{c} \rightarrow Z$ exists iff some multiple of $K_{Y}+D_{Y}$ is $g$-free, and then $Y^{c} / Z$ is given as the image of $Y / Z$ under $m\left(K_{Y}+D_{Y}\right)$ for suitable $m>0$.
2.22.4 Remark. (2.19) implies that if $g: Y \rightarrow Z$ is the $\log$ canonical model of $(X, D)$ and $E \subset Y$ is a $g$-exceptional divisor then $a(E, D)<-1$. For such divisors the coefficient in $\mathcal{F}$ is -1 , which explains why $Y$ is independent of $\mathcal{F}$.

The proof relies on the following variant of [Shokurov91, 1.5.5-6].
2.23 Theorem. Let $g: Y \rightarrow Z$ be a weak $\log$ canonical model of $f: X \rightarrow Z$ as in (2.21). Let $W$ be a normal scheme, proper and birational over both $X$ and $Y$ such that the following diagram is commutative:

Let $\left\{E_{i}, F_{i}, G_{i}\right\} \subset W$ be all the exceptional divisors such that $\left\{E_{i}\right\}$ are both $\tilde{g}$ and $\tilde{f}$-exceptional, $\left\{F_{i}\right\}$ are $\tilde{f}$ exceptional but not $\tilde{g}$-exceptional and $\left\{G_{i}\right\}$ are $\tilde{g}$ exceptional but not $\tilde{f}$ exceptional, for every $i$. Set:

$$
\begin{aligned}
\tilde{f}_{*}^{-1}\left(D_{X}\right) & =\sum d_{i} D_{i}+\sum g_{i} G_{i} \\
\tilde{g}_{*}^{-1}\left(D_{\mathcal{F}, Y}\right) & =\sum d_{i} D_{i}+\sum f_{i} F_{i} .
\end{aligned}
$$

Note that the $f_{i}$ 's are the coefficients defining $D_{\mathcal{F}, Y}$.
(2.23.1) There exists a Zariski decomposition:

$$
\begin{aligned}
& K_{W}+\tilde{f}_{*}^{-1}\left(D_{X}\right)+\sum f_{i} F_{i}+\sum E_{i} \\
& \equiv \tilde{g}^{*}\left(K_{Y}+D_{\mathcal{F}, Y}\right)+\sum\left[a\left(E_{i}, D_{\mathcal{F}, Y}\right)+1\right] E_{i}+\sum\left[a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i}\right] G_{i}
\end{aligned}
$$

where $a\left(E_{i}, D_{\mathcal{F}, Y}\right)+1 \geq 0$ and $a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i} \geq 0$.
(2.23.2) If $K_{X}+D_{X}$ is log canonical, then there exists a (Zariski-type) decomposition:

$$
\begin{aligned}
& K_{W}+\tilde{f}_{*}^{-1}\left(D_{X}\right)+\sum f_{i} F_{i}+\sum E_{i} \\
& \equiv \tilde{f}^{*}\left(K_{X}+D_{X}\right)+\sum\left[a\left(F_{i}, D_{X}\right)+f_{i}\right] F_{i}+\sum\left[a\left(E_{i}, D_{X}\right)+1\right] E_{i}
\end{aligned}
$$

where $a\left(F_{i}, D_{X}\right)+f_{i} \geq 0$ and $a\left(E_{i}, D_{X}\right)+1 \geq 0$.
(2.23.3) Let $B$ be a divisor of $\mathbb{C}(X)$. Then

$$
a\left(B, D_{\mathcal{F}, Y}\right) \geq a\left(B, D_{X}\right)
$$

Furthermore if $K_{Y}+D_{\mathcal{F}, Y}$ is $g$-ample (i.e. $g$ is a log canonical model) and $\phi$ is not a morphism at the generic point of $\operatorname{Center}_{X}(B)$ then

$$
a\left(B, D_{\mathcal{F}, Y}\right)>a\left(B, D_{X}\right)
$$

Proof. The displayed formulas in (2.23.1-2) are formal equalities. The inequalities $a\left(E_{i}, D_{\mathcal{F}, Y}\right)+1 \geq 0$ and $a\left(E_{i}, D_{X}\right)+1 \geq 0$ follow from the definition of lc. $a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i} \geq 0$ follows from the definition (2.21) and $a\left(F_{i}, D_{X}\right)+f_{i} \geq 0$ from the definition (2.7).
(2.23.3) We may assume that $B$ is a divisor on $W$. From (2.23.1-2) we obtain

$$
\begin{align*}
& \tilde{f}^{*}\left(K_{X}+D_{X}\right) \\
& \equiv \tilde{g}^{*}\left(K_{Y}+D_{\mathcal{F}, Y}\right)+\sum\left[a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i}\right] G_{i}  \tag{2.23.4}\\
& \quad+\sum\left[-f_{i}-a\left(F_{i}, D_{X}\right)\right] F_{i}+\sum\left[a\left(E_{i}, D_{\mathcal{F}, Y}\right)-a\left(E_{i}, D_{X}\right)\right) E_{i} .
\end{align*}
$$

Here $\sum\left[a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i}\right] G_{i}$ is effective and $\tilde{g}^{*}\left(K_{Y}+D_{\mathcal{F}, Y}\right)$ is $\tilde{f}$-nef. The first part follows from (2.19).

Assume that $\phi$ is not a morphism at the generic point of $\operatorname{Center}_{X}(B)$. Then

$$
\operatorname{dim} \tilde{g}\left(\tilde{f}^{-1}(\tilde{f}(B))\right)>0
$$

thus $\tilde{g}^{*}\left(K_{Y}+D_{\mathcal{F}, Y}\right)$ is not numerically trivial on $\tilde{f}^{-1}(\tilde{f}(B))$. Thus again (2.19) applies.
2.24 Corollary. Let $g: Y \rightarrow Z$ be a log model of the proper morphism $f: X \rightarrow Z$. Then:
(2.24.1) If $K_{X}+D_{X}$ is $\log$ canonical, and $g: Y \rightarrow Z$ is the $\log$ canonical model of $f$, then $\phi^{-1}$ does not contract any divisor.
(2.24.2) If $g_{i}:\left(Y_{i}, D_{i}\right) \rightarrow Z \quad(i=1,2)$ are weak $\log$ canonical models of $f$ then $g_{2}$ is a weak log canonical model of $g_{1}$.
(2.24.3) If $f: X \rightarrow Z$ is a weak log canonical model, then the modification $\phi$ to the log canonical model is a morphism.
(2.24.4) Assume that $K_{X}+D_{X}$ is $\log$ canonical, $f: X \rightarrow Z$ is birational and $f$ is small or $-\left(K_{X}+D_{X}\right)$ is $f$-nef. Then $g: Y \rightarrow Z$ is a small contraction.

Proof. Let $F_{i}$ be an exceptional divisor of $\phi^{-1}$. If $K_{X}+D_{X}$ is $\log$ canonical, then by (2.23.2) $-f_{i}-a\left(F_{i}, D_{X}\right) \leq 0$, while $g: Y \rightarrow Z$ relative $\log$ canonical model implies $-f_{i}-a\left(F_{i}, D_{X}\right)>0$. This proves (2.24.1) and also (2.24.4) for $f$ small.

If $-\left(K_{X}+D_{X}\right)$ is $f$-nef, then let $L \subset Y$ be a $g$-exceptional divisor. By the above, $\phi_{*}^{-1}(L)$ is a divisor. Restrict both sides of (2.23.4) to $\tilde{g}_{*}^{-1}(L)$. The left hand side is negative, the right hand side is big + effective. Again a contradiction.
(2.24.2) Let $\psi: Y_{1} \rightarrow Y_{2}$ be the induced map. If $E_{1} \subset Y_{1}$ is $\psi$-exceptional then by (2.21)

$$
a\left(E_{1}, D_{1}\right)=\max \left\{-1, a\left(E_{1}, D_{X}\right)\right\} \leq \max \left\{-1, a\left(E_{1}, D_{2}\right)\right\}
$$

Similarly, if $E_{2} \subset Y_{2}$ is $\psi^{-1}$-exceptional then by (2.21)

$$
a\left(E_{2}, D_{2}\right)=\max \left\{-1, a\left(E_{2}, D_{X}\right)\right\} \leq \max \left\{-1, a\left(E_{2}, D_{1}\right)\right\}
$$

By assumption $\left(Y_{i}, D_{i}\right)$ are lc thus all discrepancies are at least -1 . Therefore

$$
a\left(E_{1}, D_{1}\right) \leq a\left(E_{1}, D_{2}\right), \quad \text { and } \quad a\left(E_{2}, D_{2}\right) \leq a\left(E_{2}, D_{1}\right)
$$

These together imply that $g_{2}$ is a weak $\log$ canonical model of $g_{1}$.

## A. GRASSI, J. KOLLÁR

(2.24.3) Take a common resolution as in (2.23); we have:

$$
\begin{aligned}
\tilde{g}^{*}\left(K_{Y}+D_{\mathcal{F}, Y}\right) \equiv & \tilde{f}^{*}\left(K_{X}+D_{X}\right)-\sum\left[\left(a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i}\right] G_{i}\right. \\
& -\sum\left[\left(a\left(E_{i}, D_{\mathcal{F}, Y}\right)-a\left(E_{i}, D_{X}\right)\right] E_{i}\right.
\end{aligned}
$$

Using (2.19) and (2.23.3) we obtain that $a\left(E_{i}, D_{\mathcal{F}, Y}\right)-a\left(D_{X}, E_{i}\right)=0$ and $a\left(G_{i}, D_{\mathcal{F}, Y}\right)+g_{i}=0$ for every index $i$ and thus $\tilde{g}^{*}\left(K_{Y}+D_{\mathcal{F}, Y}\right)=\tilde{f}^{*}\left(K_{X}+\right.$ $\left.D_{X}\right)$. If $\phi$ is not a morphism, then there exists a curve $C \subset W$ which is $\tilde{f}$-exceptional but not $\tilde{g}$-exceptional. Then $K_{Y}+D_{\mathcal{F}, Y} g$-ample implies

$$
0=\left(K_{X}+D_{X}\right) \cdot C=\left(K_{Y}+D_{\mathcal{F}, Y}\right) \cdot C>0
$$

which is a contradiction.
Proof of (2.22). Assume that we have two $\log$ canonical models $Y_{1}$ and $Y_{2}$. By (2.24.2-3) there are morphisms $Y_{1} \rightarrow Y_{2}$ and $Y_{2} \rightarrow Y_{1}$; these must be inverses of each other. (2.22.2) is the same as (2.24.3). Finally (2.22.3) clearly follows from (2.22.2).
2.25 Corollary. (2.25.1) Let $X_{1} \rightarrow Z$ be a modification of $f: X \rightarrow Z$ as in the diagram:

If no divisorial component $G_{i} \subset X$ is contracted by $\tau$, then a $\log$ model for $f_{1}$ is also a log model for $f: X \rightarrow Z$.
(2.25.2) Notation as in (2.23). If $K_{X}+D_{X}$ is log canonical, $r\left(K_{X}+D_{X}\right)$ is Cartier for some $r \in \mathbb{N}$ and $g: Y \rightarrow Z$ is the $\log$ canonical model, then

$$
Y=\operatorname{Proj} \oplus_{n \geq 0} f_{*} \mathcal{O}_{X}\left(n r\left(K_{X}+D_{X}\right)\right)
$$

Proof. (2.25.1) follows from the definition.
(2.25.2) Without loss of generality we can assume that $r\left(K_{Y}+D_{Y}\right)$ is also Cartier. Let $W$ be as in (2.23). $K_{Y}+D_{Y}$ is $g$-ample, thus

$$
\begin{aligned}
Y & =\operatorname{Proj} \oplus_{n \geq 0} g_{*} \mathcal{O}_{Y}\left(n r\left(K_{Y}+D_{Y}\right)\right) \\
& =\operatorname{Proj} \oplus_{n \geq 0}(g \tilde{g})_{*} \mathcal{O}_{W}\left(\tilde{g}^{*}\left(n r\left(K_{Y}+D_{Y}\right)\right)\right) \\
& =\operatorname{Proj} \oplus_{n \geq 0}(f \tilde{f})_{*} \mathcal{O}_{W}\left(\tilde{g}^{*}\left(n r\left(K_{Y}+D_{Y}\right)\right)\right) \\
& =\operatorname{Proj} \oplus_{n \geq 0}(f \tilde{f})_{*} \mathcal{O}_{W}\left(\tilde{f}^{*}\left(n r\left(K_{X}+D_{X}\right)\right)\right)
\end{aligned}
$$

$K_{X}+D_{X}$ is $\log$ canonical and thus, by (2.24.1) $\left\{F_{i}\right\}=\emptyset$. The result follows from (2.23.1-2).

We will frequently need various versions of the Minimal Model Program. Next we describe a general variant whose steps do not exist in complete generality but which provides the right framework in all cases that we use later.
2.26 Minimal Model Program. Let $(X, E)$ be a scheme $X$ (over a base scheme $S$ which we suppress in the notation) together with an $\mathbb{R}$-Cartier divisor $E$ (not necessarily effective). By the E-Minimal Model Program (E-MMP for short) we mean a sequence

$$
\left(X_{0}, E_{0}\right) \xrightarrow{g_{0}}\left(X_{1}, E_{1}\right) \xrightarrow{g_{1}}\left(X_{2}, E_{2}\right) \xrightarrow{g_{2}} \cdots
$$

constructed as follows.
(2.26.1) $\left(X_{0}, E_{0}\right)=(X, E)$;
(2.26.2) Assume that ( $X_{i}, E_{i}$ ) is already constructed. If $E_{i}$ is nef, we stop.
(2.26.3) If $E_{i}$ is not nef then assume that there is a contraction $f_{i}: X_{i} \rightarrow Z_{i}$ such that $-E_{i}$ is $f_{i}$-ample and $\rho\left(X_{i} / Z_{i}\right)=1$. If $f_{i}\left(E_{i}\right)$ is $\mathbb{R}$-Cartier (this happens usually when the exceptional set of $f_{i}$ is an irreducible $\mathbb{Q}$-Cartier divisor) then set $g_{i}=f_{i}$ and $\left(X_{i+1}, E_{i+1}\right)=\left(Z_{i}, f_{i}\left(E_{i}\right)\right)$. (We are stuck if $f_{i}$ does not exist.)
(2.26.4) If $f_{i}\left(E_{i}\right)$ is not $\mathbb{R}$-Cartier, then we try to find a diagram

$$
\begin{array}{ccl}
\left(X_{i}, E_{i}\right) & \xrightarrow{g_{i}} & \left(X_{i+1}, E_{i+1}\right) \\
f_{i} \searrow & & \swarrow f_{i}^{+} \\
& Z_{i} &
\end{array}
$$

with the following properties
(2.26.4.1) $f_{i}^{+}$is a small morphism,
(2.26.4.2) $E_{i+1}$ is $f_{i}^{+}$-ample,
(2.26.4.3) $E_{i+1}=\left(g_{i}\right)_{*}\left(E_{i}\right)$.

Such a diagram is called the generalized opposite or generalized flip of $f_{i}$ with respect to $E_{i}$. If $f_{i}$ itself is small then the diagram is called the opposite or flip of $f_{i}$ with respect to $E_{i}$, or an $E_{i}$-flip, or an $E$-flip. (We are stuck again if the flip does not exist.)
(2.26.5) Further terminology:
(2.26.5.1) The modification described in (2.26.4) has collected various labels since it was first introduced. The name "flip" has been traditionally used to describe the above situation when $E=K_{X}$ while "log flip" is reserved for the case of a $\log$ divisor $E=K_{X}+B_{X}$. If $K_{X_{i}}$ is $f_{i}$-trivial, then the flip of $f_{i}$ with respect to the divisor $E_{i}$ is called the $E$-flop or $E_{i}$-flop.
(2.26.5.2) $X^{+}, f^{+}$and $\phi$ are also called the "flip of $f$ ".
(2.26.5.3) The birational transform of $E_{i}$ is often denoted by $E_{i}^{+}$.
2.27 Proposition. Let $f: X \rightarrow Z$ be a small birational contraction such that $-\left(K_{X}+D_{X}\right)$ is $f$-ample; then the log canonical model of $f$ is the flip with respect to $K_{X}+D_{X}$ and conversely.

A flip or log canonical model of $f$ is also a log canonical model of $Z$ for $K_{Z}+f(D)$. Therefore the discrepancies do not decrease under flips.
Proof. This follows from (2.24.2), (2.24.4) and (2.23).
The inequality between the discrepancies is also implied by the following more general result which will be useful in many situations:
2.28 Proposition. Let $f: X \rightarrow Z$ and $g: Y \rightarrow Z$ be proper birational morphisms between varieties. Let $D \subset Z$ be a divisor and let $E_{X}$ (resp. $E_{Y}$ ) be $f$ (resp. g)-exceptional divisors. (Not necessarily effective.) Assume that
(2.28.1.1) $-\left(K_{X}+f_{*}^{-1}(D)+E_{X}\right)$ is $\mathbb{R}$-Cartier and $f$-nef;
(2.28.1.2) $K_{Y}+g_{*}^{-1}(D)+E_{Y}$ is $\mathbb{R}$-Cartier and $g$-nef;

Let $B$ be any divisor of $\mathbb{C}(Z)$ and let $b \in \operatorname{Center}_{Z}(B)$ be the generic point. Then
(2.28.2.1) $a\left(B, Y, g_{*}^{-1}(D)+E_{Y}\right) \geq a\left(B, X, f_{*}^{-1}(D)+E_{X}\right)$; and
(2.28.2.2) equality holds iff $K_{X}+f_{*}^{-1}(D)+E_{X}$ is numerically trivial on $f^{-1}(b)$ and $K_{Y}+g_{*}^{-1}(D)+E_{Y}$ is numerically trivial on $g^{-1}(b)$
Proof. Let $W$ be a normal variety such that there are proper birational morphisms $\bar{f}: W \rightarrow X$ and $\bar{g}: W \rightarrow Y$. Then

$$
M=\bar{g}^{*}\left(K_{Y}+g_{*}^{-1}(D)+E_{Y}\right)+\bar{f}^{*}\left(-\left(K_{X}+f_{*}^{-1}(D)+E_{X}\right)\right)
$$

is nef on $W / Z$. Furthermore it is supported on the exceptional locus. Thus by (2.19) $M \equiv-F$ where $F$ is an effective divisor supported on the exceptional locus of $W \rightarrow Z$. Therefore

$$
\begin{aligned}
a\left(B, Y, g_{*}^{-1}(D)+E_{Y}\right) & =a\left(B, W, \bar{g}^{*}\left(K_{Y}+g_{*}^{-1}(D)+E_{Y}\right)-K_{W}\right) \\
& \geq a\left(B, W, \bar{g}^{*}\left(K_{Y}+g_{*}^{-1}(D)+E_{Y}\right)-K_{W}+F\right) \\
& =a\left(B, W, \bar{f}^{*}\left(K_{X}+f_{*}^{-1}(D)+E_{X}\right)-K_{W}\right) \\
& =a\left(B, X, f_{*}^{-1}(D)+E_{X}\right)
\end{aligned}
$$

and strict inequality holds iff $\operatorname{Center}_{W}(B) \subset \operatorname{Supp} F$. Thus (2.28.2.1) is clear and (2.28.2.2) follows from (2.19.2).
2.28.3 Remark. (2.28.3.1) We will frequently use the above result in the special case when $f$ or $g$ is an isomorphism. If $f: X \rightarrow Z=Y$ is an extremal divisorial contraction then the result says that discrepancies increase for divisors whose center is contained in the exceptional divisor of $f$.
(2.28.3.2) It is easy to see that (2.28) also holds if $X, Y, Z$ satisfy (2.6.1) and $f$ and $g$ are birational in the sense of (2.6.2).

### 2.29 Proposition.

(2.29.1) Let $\left(X, D_{X}\right)$ be klt and $f: X \rightarrow Z$ a small birational contraction. Assume that $g: Y \rightarrow Z$ is a weak $\log$ canonical model, as in (2.23.3). Then the flip of $f$ exists.
(2.29.2) Let $g: Y \rightarrow Z$ be a weak $\log$ canonical model of $f: X \rightarrow Z$. Assume that $\rho(X / Z)=1$ and either $X$ is $\mathbb{Q}$-factorial or $g$ is projective. If $g$ is small then $g$ is the flip of $f: X \rightarrow Z$.

Proof. (29.1) If $\left(X, D_{X}\right)$ is klt then $g$ is small by (2.24.4) and the Base Point Free Theorem [KMM87, 3-3-1] applies: thus the flip exists.
(2.29.2) Up to a constant multiple, $K_{Y}+D_{Y}$ is the only relative divisor on $Y$. Thus $K_{Y}+D_{Y}$ is ample and the flip exists.

Shokurov introduces a systematic method of decreasing the coefficients of $D$ while preserving the intersection numbers with the exceptional curves of $f$ and preserving rationality under an extra condition.
2.30 Definition. Let $f: X \rightarrow S$ be a contraction and $K+D$ a $\log$ divisor on $X$. We say that $D$ is an LSEPD (=Locally (over $S$ ) the Support of an Effective Principal Divisor) divisor if the following holds: for every $s \in S$ there is an open neighborhood $s \in U_{s} \subset S$ and a regular function $h_{s} \in \mathcal{O}\left(U_{s}\right)$ such that

$$
f^{-1}\left(U_{s}\right) \cap\llcorner D\lrcorner \subset \operatorname{Supp}\left(f^{*} h_{s}=0\right) \subset f^{-1}\left(U_{s}\right) \cap\ulcorner D\urcorner=f^{-1}\left(U_{s}\right) \cap \operatorname{Supp} D .
$$

I.e., $\operatorname{Supp}\left(f^{*} h_{s}=0\right)$ contains every component of $D$ which has coefficient 1 and $\operatorname{Supp}\left(f^{*} h_{s}=0\right)$ is contained in the support of $D$.

### 2.31 Remark.

(2.31.1) Let $f: Y \rightarrow S$ be a small contraction such that $\rho(Y / S)=1$, $R^{1} f_{*} \mathcal{O}_{Y}=0$ and $Y$ is $\mathbb{Q}$-factorial. A reduced boundary $D$ is LSEPD if and only if
either all the components of $D$ are numerically zero with respect to $f$, or at least one component is $f$-positive and one $f$-negative.
(2.31.2) Let $X \xrightarrow{h} Z \rightarrow S$ be proper morphism. Let $D_{X}$ (resp. $D_{Z}$ ) be divisors on $X$ (resp. $Z$ ). Then
(2.31.2.1) $D_{X}$ LSEPD $\Rightarrow h_{*}\left(D_{X}\right)$ LSEPD;
(2.31.2.2) $D_{Z}$ LSEPD $\Rightarrow h^{*}\left(D_{Z}\right)$ LSEPD;
(2.31.2.3) Assume that $X^{+} \rightarrow Z$ is the opposite of $X \rightarrow Z$. Then $D_{X}$ LSEPD $\Rightarrow D_{X}^{+}$LSEPD.

Next we prove some results which allow us to change $D$ without changing the log flip.
2.32 Proposition. Let $f: X \rightarrow Z$ be a small morphism.
(2.32.1) If $\rho(X / Z)=1$ and $R^{1} f_{*} \mathcal{O}_{X}=0$, then the opposite of $f$ with respect to $E$ does not depend on the choice of $E=\sum e_{i} E_{i}$. In particular we are free to increase or decrease the coefficients of $E$ as long as $-E$ remains $f$-ample..
(2.32.2) Let $f:(X, D) \rightarrow Z$ be log terminal, with $D$ LSEPD. Then there exists a divisor $D^{\prime}$ such that $K_{X}+D^{\prime}$ is klt and $D^{\prime}$ is $f$ - equivalent to $D$.

Proof. (2.32.1) If $E$ and $\alpha E^{\prime}(\alpha>0)$ are numerically equivalent over $Z$ then the opposite with respect to $E$ is the same as the opposite with respect to $E^{\prime}$.
(2.32.2) If $D$ is LSEPD and $K+D$ lt then there exists a positive number $\epsilon$ such that $D-\epsilon(f \circ h=0)$ is effective, $K_{X}+D-\epsilon(f \circ h=0)$ is lt and $\llcorner D-\epsilon(f \circ h=0)\lrcorner=\emptyset$.
2.33 Proposition. Let $f: X \rightarrow Z$ be a small morphism with $Z$ affine. Assume that $K_{X}+d D+D^{\prime}$ is lc (resp. plt) where $D$ is a Weil divisor. Let $n \in \mathbb{N}$. Then there is a reduced divisor $\tilde{D}$ such that
(2.33.1) $\tilde{D} \sim n D$ (hence $K_{X}+d D+D^{\prime} \equiv K_{X}+\frac{d}{n} \tilde{D}+D^{\prime}$ );
(2.33.2) $K_{X}+\frac{d}{n} \tilde{D}+D^{\prime}$ is also lc (resp. plt).

Proof. Let $\bar{D}$ be a general element of the linear system $|n f(D)|$ on $Z$. Since $Z$ is affine, $\bar{D}$ is reduced. Let $\tilde{D}$ be the birational transform of $\bar{D}$. $\tilde{D} \sim n D$ since $f$ is small. Let $g: Y \rightarrow X$ be any $\log$ resolution with exceptional divisors $E_{i}$. Then

$$
g_{*}^{-1}(\tilde{D}) \sim g_{*}^{-1}(n D)+\sum e_{i} E_{i},
$$

where $e_{i} \geq 0$. Thus

$$
a\left(E_{i}, \frac{d}{n} \tilde{D}+D^{\prime}\right)=a\left(E_{i}, d D+D^{\prime}\right)+\frac{d}{n} e_{i} .
$$

We will use the following two special cases:
2.34 Corollary. Let $f: X \rightarrow Z$ be a small morphism where $Z$ is affine. Assume that $K_{X}+D$ is lc (resp. plt). Then
(2.34.1) There is a divisor $\bar{D}$ such that $K_{X}+D \equiv K_{X}+\bar{D},\llcorner\bar{D}\lrcorner=\emptyset$ and $K_{X}+\bar{D}$ is lc (resp. plt).
(2.34.2) Assume that $D$ is a Weil divisor. There is a Weil divisor $\tilde{D}$ such that $K_{X}+D \equiv K_{X}+\frac{1}{2} \tilde{D}$ and $K_{X}+\frac{1}{2} \tilde{D}$ is lc (resp. plt).

The following result will be needed in Chapters 5 and 18.
2.35 Proposition. Let $(X, B)$ be lc and let $f: X \rightarrow Y$ be proper and birational. Then there are only finitely many $f$-extremal rays if one of the following conditions are satisfied:
(2.35.1) ( $X, B$ ) is plt and $\llcorner B\lrcorner$ does not contain any exceptional divisors;
(2.35.2) $(X, B)$ is lt outside $\llcorner B\lrcorner$ and $B$ is $L S E P D$ with respect to $f$.

Proof. (see [KMM87,4-2-4]) Assume (2.35.2). The problem is local on $Y$ so by shrinking $Y$ we may assume that there is an effective principal divisor $M \subset Y$ such that

$$
\operatorname{Supp}\llcorner B\lrcorner \subset \operatorname{Supp} f^{*} M \subset \operatorname{Supp} B
$$

Thus $\left(X, B-\epsilon f^{*} M\right)$ is klt for $0<\epsilon \ll 1$ and has the same extremal rays as ( $X, B$ ). Therefore (2.35.1) implies (2.35.2).

Let $\mathcal{O}_{X}(1)$ be $f$-ample. Choose $H \in\left|\mathcal{O}_{X}(-1)\right|$ such that $\operatorname{Supp} H$ and Supp $\llcorner B\lrcorner$ do not have common irreducible components. Thus $(X, B+\epsilon H)$ is still plt for $0<\epsilon \ll 1$. By the cone theorem [KMM87,4-2-1] if $M$ is $f$-ample then there are only finitely many ( $K+B+\epsilon H$ )-extremal rays $R$ such that $R \cdot(B+\epsilon H+M) \leq 0$. Choose $M=\epsilon(-H)$ to conclude.

# 3. CLASSIFICATION OF LOG CANONICAL SURFACE SINGULARITIES: ARITHMETICAL PROOF 

Valery Alexeev

(3.0.0). Notation. Let $(X, P)$ be a germ of a normal surface singularity and $B=\sum b_{i} B_{i}$ a formal sum of irreducible Weil divisors, passing through $P$, with rational coefficients $0 \leq b_{i} \leq 1$. Since $X$ is normal, we can assume that $P$ is the only singularity of $X$. Also, we have a well defined linear equivalence class of canonical Weil divisors $K_{X}$.

We use the usual definitions for log canonical, log terminal and purely log terminal (2.13).
(3.0.1). If $B=\emptyset$ and the characteristic of the base field is $0, \log$ terminal singularities of surfaces are the same as quotient singularities [Kawamata84] and were classified by [Brieskorn68]. [Iliev86] contains an arithmetical proof.

In the case $B$ is reduced, i.e. all the $b_{i}=1$, [Kawamata88] classified all log canonical and log terminal singularities (the latter turn out to be also purely log terminal with one trivial exception: when $X$ is nonsingular and $B$ consists of two normally crossing nonsingular curves). This classification is given in Fig.3. The notation is explained in (3.1).

The proof of [Kawamata88] is slightly tricky and uses the log canonical cover of $(X, P)$. Arithmetical proofs were given in [Sakai87] for the case $b_{i}=0$ and by S. Nakamura in an appendix to [Kobayashi90].
(3.0.2). Here we suggest a purely arithmetical and quite elementary approach for the classification. The idea is the following: let $f: Y \rightarrow X$ be the minimal resolution of the singularity $(X, P)$ (a priori not a good resolution of $(X, P)$ ).

Let $f_{*}^{-1} C \subset Y$ denote the birational transform of a curve $C \subset X$. Write

$$
K_{Y}+\sum f_{*}^{-1} B_{i}+\sum E_{j}=f^{*}\left(K_{X}+\sum B_{i}\right)+\sum a_{j} E_{j} .
$$

S. M. F.

## V. ALEXEEV

Then for any $j=1, \ldots, n$, by the adjunction formula, we have

$$
\begin{aligned}
2 p_{a}\left(E_{j}\right) & =E_{j}\left(K_{Y}+E_{j}\right)+2= \\
& =E_{j}\left(f^{*}\left(K_{X}+B\right)+\sum_{k} a_{k} E_{k}-\sum f_{*}^{-1} B_{i}-\sum_{k \neq j} E_{k}\right)+2= \\
& =E_{j}\left(\sum a_{k} E_{k}-\sum f_{*}^{-1} B_{i}-\sum_{k \neq j} E_{k}\right)+2
\end{aligned}
$$

Therefore we get the following system of $n$ linear equations in $n$ variables

$$
\begin{equation*}
\sum_{k=1}^{n} a_{k} E_{k} \cdot E_{j}=-c_{j}, \tag{*}
\end{equation*}
$$

where $c_{j}=2-2 p_{a}\left(E_{j}\right)-\left(\sum f_{*}^{-1} B_{i}+\sum_{k \neq j} E_{k}\right) E_{j}$. Equivalently,

$$
\begin{equation*}
\sum_{k=1}^{n}\left(a_{k}-1\right) E_{k} \cdot E_{j}=-d_{j}, \tag{**}
\end{equation*}
$$

where $d_{j}=2-2 p_{a}\left(E_{j}\right)+E_{j}^{2}-\sum f_{*}^{-1} B_{i} \cdot E_{j}$.
(3.0.3). Now our strategy is very simple: solve the system (*), find the $a_{k}$ and check the conditions $a_{k} \geq 0$.
(3.0.4). Some of the formulas for the coefficients $a_{k}$ are contained in [Alexeev89, 4.7,4.8]. Note also that in the $\log$ terminal case with $B=\emptyset$, our treatment.has some intersections with [lliev86]. However, our proof is more explicit and direct.
J. Kollár points out that the present proof works in any characteristic. This follows from the fact that the system (*) has a unique solution independent of the characteristic of the base field.

### 3.1. Solution of (*).

(3.1.0). First, note that (*) does have a unique solution since by [Mumford61] the matrix $\left(E_{k} \cdot E_{j}\right)$ is negative definite.
(3.1.1). The weighted dual graph $\Gamma$ of the resolution $f: Y \rightarrow X$ is the following: each curve $E_{j}$ corresponds to a vertex $v_{j}$. Two vertices $v_{j_{1}}$ and $v_{j_{2}}$ are connected by an edge of weight $m$ if the corresponding curves intersect: $E_{j_{1}} \cdot E_{j_{2}}=m$. Each vertex $v_{j}$ has a positive weight $n_{j}=-E_{j}^{2}$.

Since the resolution $f$ is minimal, we have $d_{j}=2-2 p_{a}\left(E_{j}\right)+E_{j}^{2}-$ $\sum f_{*}^{-1} B_{i} E_{j} \leq 0$ for all $j$.
(3.1.2). By (2.19.3) every coefficient of the inverse matrix of $\left(E_{k} \cdot E_{j}\right)$ is strictly negative. Therefore, $(* *)$ implies that either all $d_{j}=0$, and then for all $k, a_{k}-1=0$ or at least one $d_{j}<0$, and for all $k, a_{k}-1<0$. The former happens only if all $p_{a}\left(E_{j}\right)=0, E_{j}^{2}=-2$ and $E_{j} \cdot \sum f_{*}^{-1} B_{i}=0$. Such singularities (and the corresponding graphs) are called $D u$ Val singularities (resp. Du Val graphs).

The following result is easy.
(3.1.3). Lemma. (cf. [Alexeev89,3.2(ii-iii)]) Let $\Gamma$ be a weighted graph corresponding to a minimal resolution, in particular such that all $d_{j} \leq 0$. Let $\Gamma^{\prime} \subset \Gamma, \Gamma^{\prime} \neq \Gamma$ be a subgraph in the sense that all the vertices of $\Gamma^{\prime}$ are at the same time vertices of $\Gamma$ with the same weight $n_{j}$, the weights of edges of $\Gamma^{\prime}$ and $p_{a}$ of vertices in $\Gamma^{\prime}$ do not exceed the corresponding weights and $p_{a}$ in $\Gamma$, and $E_{j} \cdot \sum f_{*}^{-1} B_{i}$ in $\Gamma^{\prime}$ do not exceed the corresponding $E_{j} \cdot \sum f_{*}^{-1} B_{i}$ in $\Gamma$.

Then the corresponding coefficients satisfy $a_{k} \leq a_{k}^{\prime}$ and if $\Gamma$ is not a $D u$ Val graph, then $a_{k}<a_{k}^{\prime}$.

Proof. Compare the corresponding systems ( $* *$ ) of linear equations and use (3.1.2).
(3.1.4). Suppose that $\Gamma^{\prime}=\left\{v_{1}\right\}$ and $p_{a}\left(E_{1}\right)=1$. Then in $(*) c_{1}=2-$ $2 p_{a}\left(E_{1}\right)-0=0$ and $a_{1}^{\prime}=0$. If $E_{1}$ is a smooth elliptic curve, this is Case 4 of Fig.3. If $E_{1}$ is a rational curve with a node then after a single blow up we are in Case 5 of Fig.3. If $E_{1}$ is a rational curve with a cusp it is easy to show that after two blow ups one gets a log discrepancy $a_{3}=-1$, so this is not a log canonical singularity.
(3.1.5). Suppose that $\Gamma^{\prime}=\left\{v_{1}, v_{2}, \ldots, v_{l}\right\}$ is a circle of smooth rational curves. Then in $(*) c_{j}=2-0-2=0$ and all $a_{j}^{\prime}=0$. This is Case 5 of Figure 3. Note that all the curves $E_{j}$ should intersect normally: if a circle contains two or three vertices and two corresponding curves have a common tangent, or three curves intersect at one point, then two or one blow ups give a $\log$ discrepancy $a_{3}^{\prime}=-1$.
(3.1.6). Now (3.1.2-5) imply that:
(3.1.6.1). The graph of a log canonical singularity does not contain a vertex $v_{j}$ with $p_{a}\left(E_{j}\right)>1$ or an edge of weight $>2$.

## V. ALEXEEV

(3.1.6.2). If $\Gamma \neq \Gamma^{\prime}$ as in (3.1.4) or (3.1.5), then $\Gamma$ contains only vertices that correspond to smooth rational curves, all edges are simple, i.e. of weight 1 , and $\Gamma$ is a tree.

From now on we always assume that we are in this final case.
(3.1.7). For any subgraph $\Gamma^{\prime} \subset \Gamma$, we define $\Delta^{\prime}=\Delta\left(\Gamma^{\prime}\right)$ as the absolute value of the determinant of the submatrix $\left(E_{k} \cdot E_{j}\right)$, made up by the columns and rows corresponding to the vertices of $\Gamma^{\prime}$.

Note that if $\Gamma^{\prime}$ is a disjoint union of graphs $\Gamma_{1}$ and $\Gamma_{2}$, then $\Delta^{\prime}=\Delta_{1} \cdot \Delta_{2}$. We set $\Delta(\emptyset)=1$ by definition.

The following lemmas are easy exercises.
3.1.8 Lemma. Let $\Gamma$ be a graph with simple edges, $v$ a vertex of $\Gamma$ of weight $n$, and $v_{1}, \ldots, v_{s}$ the vertices adjacent to $v$. Then

$$
\Delta(\Gamma)=n \cdot \Delta(\Gamma-v)-\sum_{i} \Delta\left(\Gamma-v-v_{i}\right) .
$$

3.1.9 Lemma. Let $\Gamma$ be a tree with simple edges, $v_{j_{1}}, v_{j_{2}}$ two vertices of $\Gamma$. Then the $\left(j_{1}, j_{2}\right)$ cofactor of the matrix $\left(E_{k} \cdot E_{j}\right)$ is

$$
A_{j_{1} j_{2}}=(-1)^{j_{1}+j_{2}} M_{j_{1} j_{2}}=-(-1)^{n} \Delta\left(\Gamma-\left(\text { path } \quad \text { from } \quad v_{j_{1}} \quad \text { to } \quad v_{j_{2}}\right)\right)
$$

Note that since $\Gamma$ is a tree there is a unique (shortest) path joining $v_{j_{1}}$ and $v_{j_{2}}$.
(3.1.10). The previous lemma gives the solution of (*):
$(* * *)$

$$
\begin{aligned}
a_{j} & =\frac{1}{\Delta(\Gamma)} \sum_{k=1}^{n} \Delta\left(\Gamma-\left(\text { path from } \quad v_{j} \quad \text { to } \quad v_{k}\right)\right) \cdot c_{k} \\
c_{k} & =2-\left(\sum f_{*}^{-1} B_{i}+\sum_{l \neq k} E_{l}\right) E_{k}
\end{aligned}
$$

Here $\left(\sum f_{*}^{-1} B_{i}+\sum_{l \neq k} E_{l}\right) E_{k}$ is the number of connections of the vertex $v_{k}$ with adjacent vertices (among $\sum f_{*}^{-1} B_{i}$ and the other $E_{l}$ ). Therefore, $c_{k}=0$ if and only if $v_{k}$ has exactly 2 neighbours, $c_{k}=1$ if it has 1 neighbour and $c_{k}<0$ if if has $\geq 3$ neighbours. By $(* * *), a_{j}$ is a sum of $c_{k}$ with positive coefficients. We are interested in the cases when $a_{j} \geq 0$, therefore we call vertices with $c_{k}=1$ (resp. $c_{k}<0$ ) bonus (resp. penalty) vertices.

Now our aim is to simplify the use of the formulas ( $* * *$ ).
(3.1.11). We need the following well known description of weighted chains. Every weighted chain with positive integer weights (from the left to right) $n_{1}, \ldots, n_{s} \geq 2$ corresponds in unique way to the pair ( $\Delta, q$ ), where $\Delta=\Delta(\Gamma)$ and $1 \leq q<\Delta$ is an integer coprime to $\Delta$ defined by:

$$
\frac{\Delta}{q}=n_{1}-\frac{1}{n_{2}-\frac{1}{\cdots \frac{1}{n_{s}}}}
$$

Let us show how to get this description. Let $v$ be the end vertex of the chain $\Gamma$. Then by (3.1.8), $\Delta=\Delta(\Gamma)$ can be expressed in terms of $q=\Delta(\Gamma-v)$ and $\Delta\left(\Gamma-v-v_{1}\right)$, then $\Delta(\Gamma-v)$ can be expressed in terms of $\Delta\left(\Gamma-v-v_{1}\right)$ and $\Delta\left(\Gamma-v-v_{1}-v_{2}\right)$ and so on, the last determinant will be $\Delta(\emptyset)=1$. One can easily see that this procedure is nothing other than the Euclidean algorithm for finding the greatest common divisor, so $(\Delta, q)=1$, and one gets the given formula.
3.1.12 Lemma. Suppose that a graph $\Gamma$ contains a subgraph $\Gamma^{\prime}$ such that $\Gamma^{\prime}$ is a chain with weights $n_{j} \geq 2$ and the interior vertices of this chain have no other neighbors in $\Gamma$ or $\sum B_{j}$. Let $v_{j_{1}}$ be one of the middle vertices, $a_{j_{1}}$ the corresponding log discrepancy of $\Gamma$. Then the graph of the function $a_{j}$ at the vertex $v_{j_{1}}$ is concave up if $a_{j_{1}} \geq 0$ and is concave down if $a_{j_{1}} \leq 0$.

Proof. Note that from (*)

$$
a_{j_{1}-1}-n_{j_{1}} a_{j_{1}}+a_{j_{1}+1}=0,
$$

so that

$$
\left|a_{j_{1}}\right|=\left|\frac{a_{j_{1}-1}+a_{j_{1}+1}}{n_{j_{1}}}\right| \leq\left|\frac{a_{j_{1}-1}+a_{j_{1}+1}}{2}\right| .
$$

The rest is obvious.
3.1.13 Lemma. Let $\Gamma$ be a tree with simple edges and all weights $n_{j} \geq 2$ (all these conditions hold in our situation). Then all the log discrepancies of $\Gamma$ are nonnegative (resp. positive) if and only if the same holds for all vertices with at least 3 neighbours and for all vertices neighbouring $\sum f_{*}^{-1} B_{i}$.

Proof. Indeed, if $\Gamma^{\prime} \subset \Gamma$ is a subchain such that each middle vertex has exactly 2 neighbours and one of this middle vertices has $a_{j_{1}} \leq 0$ (resp. $a_{j}<0$ ), then by (3.1.12) the same holds for the ends of $\Gamma^{\prime}$.

## V. ALEXEEV

Moreover, we can exclude the vertices with exactly 1 neighbour, because from (*) we have

$$
a_{j_{1}+1}-n_{j_{1}} a_{j_{1}}=-1
$$

and $a_{j_{1}} \leq 0$ implies $a_{j_{1}+1}<a_{j_{1}}$.
(3.1.14). We explain the notation of Fig.3. We consider a minimal resolution $f: Y \rightarrow X$ (with the exception of Case 5). o denotes an exceptional curve of $f$, • denotes (local branches of) $B_{i}$. Long empty ovals denote any chain $(\Delta, q)$, attached at an end.
3.2. The case $B=\emptyset$. We first consider several simple possibilities for the graph $\Gamma$
(3.2.1). Let $\Gamma$ be a chain. Then by (3.1.13) $\Gamma$ corresponds to a log terminal singularity, because none of the vertices has $\geq 3$ neighbours.
(3.1.10) gives the formula for the $\log$ discrepancies. Let $v_{j}$ be a vertex of $\Gamma$, so that $\Gamma-v_{j}=\Gamma_{1}-\Gamma_{2}$ is a disjoint union of two chains ( $\Gamma_{1}$ or $\Gamma_{2}$ could be empty), let $\Delta_{1}, \Delta_{2}$ be the corresponding (absolute values of) the determinants $(\Delta(\emptyset)=1$ by definition). In our situation we have only 2 bonus vertices, namely the ends of the chain $\Gamma$. Therefore

$$
a_{j}=\frac{1}{\Delta}\left(\Delta_{1}+\Delta_{2}\right)=\frac{\Delta_{1} \Delta_{2}}{\Delta}\left(\frac{1}{\Delta_{1}}+\frac{1}{\Delta_{2}}\right) .
$$

This is Case 1 of Fig.3.
(3.2.2). Let $\Gamma$ be a graph having a single fork at a vertex $v_{j}$ and suppose that $\Gamma-v_{j}=\Gamma_{1}+\Gamma_{2}+\Gamma_{3}$, and $\Delta_{i}=\Delta\left(\Gamma_{i}\right)$ for $i=1,2,3$. In order for $\Gamma$ to correspond to a log terminal (resp. log canonical) singularity one should have $a_{j}>0$ (resp. $a_{j} \geq 0$ ). In this situation we have 3 bonus vertices, namely the simple ends of $\Gamma_{1}, \Gamma_{2}, \Gamma_{3}$ and 1 penalty vertex which is $v_{j}$ itself. Therefore, by (3.1.10) one has

$$
\begin{aligned}
a_{j} & =\frac{1}{\Delta}\left(\Delta_{1} \Delta_{2}+\Delta_{2} \Delta_{3}+\Delta_{3} \Delta_{1}-\Delta_{1} \Delta_{2} \Delta_{3}\right)= \\
& =\frac{\Delta_{1} \Delta_{2} \Delta_{3}}{\Delta}\left(\frac{1}{\Delta_{1}}+\frac{1}{\Delta_{2}}+\frac{1}{\Delta_{3}}-1\right) .
\end{aligned}
$$

So this is a log terminal singularity in the cases

$$
\text { (3.2.2.1). } \quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(2,2, n), \quad n \geq 2
$$

(3.2.2.2). $\quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(2,3,3)$
(3.2.2.3). $\quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(2,3,4)$
(3.2.2.4). $\quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(2,3,5)$
and a $\log$ canonical (but not log terminal) singularity in the cases
(3.2.2.5). $\quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(2,3,6)$
(3.2.2.6). $\quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(2,4,4)$
(3.2.2.7). $\quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}\right)=(3,3,3)$

This gives Cases 2 and 6 of Fig.3.
(3.2.3). Now let $\Gamma$ be a graph with a single fork at the vertex $v_{j}$ and suppose that $\Gamma-v_{j}=\Gamma_{1}+\Gamma_{2}+\Gamma_{3}+\Gamma_{4}, \Delta_{i}=\Delta\left(\Gamma_{i}\right)$ for $i=1, \ldots, 4$.

Then

$$
a_{j}=\frac{\Delta_{1} \Delta_{2} \Delta_{3} \Delta_{4}}{\Delta}\left(\frac{1}{\Delta_{1}}+\frac{1}{\Delta_{2}}+\frac{1}{\Delta_{3}}+\frac{1}{\Delta_{4}}-2\right)
$$

and gives a $\log$ canonical singularity only if
$(3.2 .3 .1) \quad\left(\Delta_{1}, \Delta_{2}, \Delta_{3}, \Delta_{4}\right)=(2,2,2,2)$
This is Case 8 of Fig.3.
(3.2.4). In the case of graph $\Gamma$ with a single fork at a vertex $v_{j}$, breaking up $\Gamma$ into $N \geq 5$ subgraphs we get a non-log canonical singularity, because

$$
a_{j}=\frac{\prod \Delta_{i}}{\Delta}\left(\sum_{i=1}^{N} \frac{1}{\Delta_{i}}-(N-2)\right)<0
$$

for $\Delta_{i} \geq 2$ and $N \geq 5$.
(3.2.5). Now suppose that we are in the situation of Fig. 1 of a graph $\Gamma$ with at least 2 forks, one of them at the vertex $v_{j}$. Suppose that $\Gamma-v_{j}=\Gamma_{1}+\Gamma_{2}+\Gamma_{3}$, and let $\Delta_{1}, \Delta_{2}, \Delta_{3}, \Delta_{A}, \Delta_{B}$ be the corresponding determinants. Then by (3.1.10),

$$
a_{j}=\frac{\Delta_{1} \Delta_{2} \Delta_{3}}{\Delta}\left(\frac{1}{\Delta_{1}}+\frac{1}{\Delta_{2}}+\frac{1-\left(\Delta_{A}-1\right)\left(\Delta_{B}-1\right)}{\Delta_{3}}-1\right)
$$

This is nonnegative (actually, equal to zero) only in the case

$$
\Delta_{1}=\Delta_{2}=\Delta_{A}=\Delta_{B}=2
$$

By (3.1.10), this is also the sufficient condition for $\Gamma$ to give a $\log$ canonical singularity. This is Case 7.

Fig. 1
(3.2.6). Using (3.1.10) one can easily show that in the graphs of Fig. 2 the marked vertices have negative log discrepancies, hence these graphs define non-log canonical singularities.

Fig. 2
3.2.7 Lemma. If $\Gamma$ corresponds to a log terminal (log canonical) singularity then $\Gamma$ is one of the graphs listed in (3.2.1-2.5).

1st proof. (3.2.5) gives the general rule for what happens to a log discrepancy when we add an additional fork: the term, denote it by $T$, that corresponds to the part of the graph after the new fork is changed to a number

$$
T \cdot\left(\Delta_{A}-\Delta_{B}\left(\Delta_{A}-1\right)\right)
$$

with the corresponding $\Delta_{A}, \Delta_{B} \geq 1$. The other terms don't change.

Therefore, starting from (3.2.3), (3.2.4) or (3.2.6), adding a fork always gives a negative log discrepancy.

2nd proof. By (3.1.3) the subgraph $\Gamma^{\prime} \subset \Gamma$ also defines a log canonical singularity. Therefore $\Gamma$ cannot have subgraphs as in (3.2.4) or (3.2.6).
(3.2.8). Note that Case 8 is essentially a subcase of 7 .

### 3.3. The case $B \neq \emptyset$.

(3.3.1). In addition to the restrictions of (3.2) we have to consider additional penalties for the connections with $f_{*}^{-1} B$. Now it is an easy excercise to get the remaining Cases of Fig.3.
(3.3.2). From Fig. 3 one can see that the minimal resolution is a good resolution for $K+B$. Note that in Case 9 with a chain containing a single vertex $v_{1}$, the curves corresponding to the black vertices do not intersect $E_{1}$. Otherwise, a single blow up gives a log discrepancy $a_{2}=-1$.
(3.3.3). Note that in the Case 9 of Fig. 3 all the discrepancies are zero because we have neither bonuses nor penalties.
(3.3.4). The index of a rational singularity, i.e. the least natural number $N$ such that $N K_{X}$ is a Cartier divisor, is at the same time the least common denominator of all the $\log$ discrepancies $a_{j}$. One can easily see that in the Cases 6-8 indices are $2,3,4$ or 6 .

### 3.4. Final remarks.

(3.4.1). Note that the only restriction on the unmarked weights on Fig. 3 is that the quadratic form of the whole graph $\Gamma$ should be negative definite. This is essential only in Cases $6-8$ (where at least one weight should be $>2$ ), and also in Case 5 (where either all weights are at least two and at least one at least three; or there are two vertices, one of them has weight one and the other has weight at least five).

An easy case by case check shows that in Cases 1-3 and 6-10 any (contractible) graph defines a rational singularity, so by [Artin66] a configuration can be contracted to a normal singular point. In cases $4-5$ if the quadratic form is negative definite, then a configuration can be contracted in the analytic situation. In the algebraic situation this is a necessary condition (but not sufficient).
(3.4.2). Our method allows one in principle to classify log terminal or log canonical surface singularities ( $X, K+B$ ) when $B$ may have fractional coefficients with denominators $2,3, \ldots$, if this should turn out to be necessary. There will be a large number of new cases.
$K+B$ is $\log$ terminal, $B$ is reduced

# 4. TERMINATION OF CANONICAL FLIPS 

János Kollár and Kenji Matsuki

The aim of this chapter is to study flops and flips for terminal and canonical threefolds. First we prove the basic finite generation theorem of [Reid83]. The second main result is termination of flips (and flops) for canonical pairs ( $X, D$ ) (4.10). We start with some general results that hold for arbitrary schemes.
4.1 Definition. Let $X$ be a normal scheme. A small modification of $X$ is a proper birational morphism $f: Y \rightarrow X$ such that $Y$ is normal and the exceptional set of $f$ has codimension $\geq 2$. We usually exclude the trivial case $Y \cong X$.

The following proposition relates projective small modifications to the divisor class group Weil $(X)$ (cf. (16.3.1)).
4.2 Proposition. [Kawamata88,3.1] Let $X$ be a normal scheme and let $D$ be a Weil divisor on $X$ (not necessarily effective). The following two statements are equivalent:
(4.2.1) $\sum_{m=0}^{\infty} \mathcal{O}_{X}(m D)$ is a finitely generated $\mathcal{O}_{X}$-algebra.
(4.2.2) There is a small modification $f: Y \rightarrow X$ such that $D^{\prime}$, the birational transform of $D$ on $Y$, is $\mathbb{Q}$-Cartier and $f$-ample.

Furthermore $f$ is nontrivial iff no positive multiple of $D$ is Cartier.
Proof. Assume that $f: Y \rightarrow X$ exists. Let $C \subset Y$ be the exceptional set. First we claim that

$$
\begin{equation*}
f_{*} \mathcal{O}_{Y}\left(m D^{\prime}\right)=\mathcal{O}_{X}(m D) \quad \text { for } m \geq 0 \tag{4.2.3}
\end{equation*}
$$

It is always true that $f_{*} \mathcal{O}_{Y}\left(m D^{\prime}\right) \subset \mathcal{O}_{X}(m D)$. Let $C \subset Y$ be the exceptional set of $f$. Let $s: \mathcal{O}_{X} \rightarrow \mathcal{O}_{X}(m D)$ be a section. We can pull it back to a section

$$
s: \mathcal{O}_{Y-C} \rightarrow \mathcal{O}_{Y-C}\left(m D^{\prime}\right)
$$

S. M. F.

Since $C$ has codimension $\geq 2$, this extends to a section $s: \mathcal{O}_{Y} \rightarrow \mathcal{O}_{Y}\left(m D^{\prime}\right)$. This proves (4.2.3). Then (4.2.1) follows since $D^{\prime}$ is $f$-ample, and hence

$$
\sum_{m=0}^{\infty} f_{*} \mathcal{O}_{Y}\left(m D^{\prime}\right)
$$

is finitely generated.
Replacing $D$ by $r D$ for some $r>0$ we may assume that $\mathcal{O}_{X}(D)$ generates $\sum \mathcal{O}_{X}(m D)$. Let

$$
Y=\operatorname{Proj}_{X} \sum_{m=0}^{\infty} \mathcal{O}_{X}(m D)
$$

and let $D^{\prime}$ be the birational transform of $D$ on $Y$ (hence $\left.\mathcal{O}_{Y}\left(D^{\prime}\right)=\mathcal{O}_{Y}(1)\right)$. Let $C \subset Y$ be the exceptional set and assume that it contains a divisor $E$. For $m \gg 1$ we have an exact sequence

$$
0 \rightarrow f_{*} \mathcal{O}_{Y}\left(m D^{\prime}\right) \rightarrow f_{*} \mathcal{O}_{Y}\left(m D^{\prime}+E\right) \rightarrow f_{*}\left(\mathcal{O}_{Y}\left(m D^{\prime}\right) \otimes\left(\mathcal{O}_{Y}(E) / \mathcal{O}_{Y}\right)\right) \rightarrow 0
$$

since $R^{1} f_{*} \mathcal{O}_{Y}\left(m D^{\prime}\right)=0$. Therefore for $m \gg 1$

$$
\mathcal{O}_{X}(m D)=f_{*} \mathcal{O}_{Y}\left(m D^{\prime}\right) \subsetneq f_{*} \mathcal{O}_{Y}\left(m D^{\prime}+E\right)
$$

This is impossible since $\mathcal{O}_{X}(m D)$ is reflexive and

$$
\mathcal{O}_{X}(m D)\left|X-f(C)=f_{*} \mathcal{O}_{Y}\left(m D^{\prime}+E\right)\right| X-f(C)
$$

Finally, assume that $m D$ is Cartier. Then $m D^{\prime}$ and $f^{*}(m D)$ are two $\mathbb{Q}$ Cartier divisors on $Y$ which agree outside a set of codimension two. Thus $m D^{\prime}=f^{*}(m D)$. Since $D$ is $f$-ample and $f_{*} \mathcal{O}_{Y}=\mathcal{O}_{X}$, this is possible only if $Y \cong X$.
4.3 Remark. (4.3.1) If $X$ is affine, then one can always find an ideal sheaf $I \subset \mathcal{O}_{X}$ which is isomorphic to $\mathcal{O}_{X}(D)$ (as a sheaf), and then the $m^{t h}$ symbolic power of $I$ is by definition $I^{(m)} \cong \mathcal{O}_{X}(m D)$. For this reason the algebra $\sum_{m=0}^{\infty} \mathcal{O}_{X}(m D)$ is called the symbolic power algebra of $D$.
(4.3.2) The equivalent statements of (4.2) are both false in general. However it is not easy to come up with nice examples (see e.g. [Cutkosky88]).
4.4 Definition. Let $D$ be a Weil divisor on $X$. We say that finite generation holds for $D$ on $X$ if the equivalent conditions of (4.2) are satisfied.
4.5 Corollary. Let $X$ be a normal scheme and assume that $\operatorname{rank}_{\mathbb{Z}} \operatorname{Pic}(X-$ $\operatorname{Sing} X) / \operatorname{Pic}(X)=1$. Then $X$ has at most two small projective modifications.
Proof. Let $f_{i}: Y_{i} \rightarrow X$ be a small modification and let $D_{i}^{\prime}$ be an $f_{i}$-ample divisor. Let $D_{i}=f_{*}\left(D_{i}^{\prime}\right)$. Then by (4.2)

$$
Y_{i}=\operatorname{Proj}_{X} \sum_{j=0}^{\infty} \mathcal{O}_{X}\left(j D_{i}\right) .
$$

If $n D_{1} \sim m D_{2}$ for some $n, m>0$ then since Proj is unchanged on truncating a graded ring

$$
\begin{aligned}
\operatorname{Proj}_{X} \sum_{j=0}^{\infty} \mathcal{O}_{X}\left(j D_{1}\right) & \cong \operatorname{Proj}_{X} \sum_{j=0}^{\infty} \mathcal{O}_{X}\left(j n D_{1}\right) \\
& \cong \operatorname{Proj}_{X} \sum_{j=0}^{\infty} \mathcal{O}_{X}\left(j m D_{2}\right) \cong \operatorname{Proj}_{X} \sum_{j=0}^{\infty} \mathcal{O}_{X}\left(j D_{2}\right) .
\end{aligned}
$$

Therefore the two possible modifications correspond to the positive and negative parts of $\mathbb{Z}$.
4.6 Proposition. [Kawamata88,3.2] Let $X$ and $Z$ be normal, irreducible schemes and $g: Z \rightarrow X$ a finite and surjective morphism. Let $E$ be a Weil divisor on $X$ and $E_{Z}=g^{*} E$. Then finite generation holds for $E$ iff it holds for $E_{Z}$.
Proof. (Assume for simplicity that $g$ is separable.) Suppose that finite generation holds for $E$. Let $f: Y \rightarrow X$ be a small modification such that the birational transform $E^{\prime}$ of $E$ is $f$-ample. Let $p: Y_{Z} \rightarrow Y$ be the normalization of $Y \times_{X} Z$. Then $h: Y_{Z} \rightarrow Z$ is a small modification and $p^{*}\left(E^{\prime}\right)$ is $h$-ample. Also, $p^{*}\left(E^{\prime}\right)$ is the birational transform of $E_{Z}$. Thus finite generation holds for $E_{Z}$.

Assume finite generation for $E_{Z}$. Let $q: U \rightarrow Z \rightarrow X$ be the Galois closure of $Z$ over $X$ and $G$ the Galois group of $U / X$. Set $E_{U}=q^{*} E_{Z}$. By the previous case finite generation holds for $E_{U}$; thus there is a small modification $f_{U}: Y_{U} \rightarrow U$ such that the birational transform $E_{U}^{\prime}$ of $E_{U}$ is $f_{U}$-ample. Clearly $G$ acts on $Y_{U}$. Take $Y=Y_{U} / G$. $E_{U}^{\prime}$ descends to a divisor $E_{U}^{\prime} / G$ on $Y$ which is the birational transform of $E$. Thus finite generation holds for $E$.
4.7 Theorem. [Reid83] Let $X$ be a threefold with terminal singularities. Let $D \subset X$ be a Weil divisor. Then

$$
\sum_{m=0}^{\infty} \mathcal{O}_{X}(m D)
$$

is a finitely generated $\mathcal{O}_{X}$-algebra.
Proof. The problem is local, thus we may assume that $\mathcal{O}_{X}\left(m K_{X}\right) \cong \mathcal{O}_{X}$ for some $m>0$.

By (4.6) it is sufficient to prove (4.7) for the index one cover of $X$. Thus we may assume that $X$ is terminal with index one. By [Reid83] $X$ is a cDV point; thus it can be viewed as a one parameter family $g: X \rightarrow \Delta(t)$ of surfaces with DuVal singularities. By [Brieskorn71] (see also [Artin74]) there is a base change $t=s^{m}$ such that the resulting threefold $X^{\prime}=X \times_{\Delta(t)} \Delta(s)$ admits a small resolution. That is, there is a small modification $h: Y^{\prime} \rightarrow X^{\prime}$ such that $Y^{\prime}$ is smooth. By (4.6) it is sufficient to prove finite generation on $X^{\prime}$. Let $D$ be a Weil divisor on $X^{\prime}$ and let $H$ be its birational transform on $Y^{\prime}$.

We apply the $(K+\epsilon H)$-MMP on $Y^{\prime} / X^{\prime}$ with some $0<\epsilon \ll 1$ (see (2.26)). The existence of flops is given by (4.8) while termination is proved in (4.11). Finally we obtain $h^{+}: Y^{+} \rightarrow X^{\prime}$ such that $H^{+}$is $h^{+}$-nef. By Base Point Freeness [KMM87,3-1-2], there is a morphism

$$
h^{+}: Y^{+} \xrightarrow{p} \bar{Y} \xrightarrow{q} X^{\prime}
$$

such that $p\left(H^{+}\right)$is $\mathbb{Q}$-Cartier and $q$-ample. Thus $q: \bar{Y} \rightarrow X^{\prime}$ shows finite generation for $D$.
4.8 Theorem. [Reid83] Let $f: Y \rightarrow X$ be a small modification between threefolds. Assume that $Y$ has isolated $c D V$ points only and $K_{Y}$ is numerically $f$-trivial. Let $H$ be a divisor on $Y$ such that $H$ is negative on $Y / X$. Then the flop $f^{+}: Y^{+} \rightarrow X$ of $f$ with respect to $H$ exists and has isolated $c D V$ points only.
Proof. A very simple proof, due to Mori, is given in [CKM88,16.8-9].
4.9 Definition. [Kawamata91c] Let $(X, D)$ be a log variety. Assume that $K_{X}+D$ is $\mathbb{Q}$-Cartier ( $K_{X}$ need not be $\mathbb{Q}$-Cartier). We say that $(X, D)$ is terminal (resp. canonical) if $a(E, D)>0$ (resp. $\geq 0$ ) for every exceptional divisor of $\mathbb{C}(X)$ with center on $X$ (cf. (1.6)). If $D=\emptyset$, this coincides with the usual definition of terminal (resp. canonical).
4.9.1 Exercise. Let $\left(0 \in S, \sum b_{i} B_{i}\right)$ be the germ of a normal surface. Then (4.9.1.1) $\left(S, \sum b_{i} B_{i}\right)$ is terminal iff

$$
S \text { is smooth and } \sum b_{i} \text { mult }_{0} B_{i}<1
$$

Therefore if $(X, D)$ is terminal (any dimension) then $\llcorner D\lrcorner=\emptyset$ and $X$ is smooth in codimension two.
(4.9.1.2) $\left(S, \sum b_{i} B_{i}\right)$ is canonical iff either

$$
\begin{array}{ll}
S \text { is smooth and } & \sum b_{i} \text { mult }_{0} B_{i} \leq 1 ; \quad \text { or } \\
S \text { is Du Val and } & \sum b_{i} B_{i}=0 .
\end{array}
$$

From (2.28) we see that terminal is preserved under flops and flips. It is however not preserved under extremal contractions.

In the rest of this section, flips are assumed to exist whenever they are mentioned.

Next we prove the termination of a sequence of flips for terminal 3-folds $(X, D)$. The flop version was first proved by [Kawamata88] for a special case, then in general by [Kollár89]. Finally [Kawamata91c] noticed that the right context is the more general form (4.10).

Here we emphasise the analogy between [Kollár89] and [Shokurov91, 4.1] whose proof is presented in Chapter 7. Roughly speaking, the proofs consist of two major steps (the $D=\emptyset$ case can be treated as a special case of (I)):
(I) Show that there is a finite set of special discrete valuations associated to the flipped curves such that the cardinality of the set (or some other invariant) drops if a flipped curve is contained in the boundary. This step shows that, after finitely many flips, no flipped curve is contained in the boundary.
(II) Now use the finiteness of the Picard number of the irreducible components of the boundary to conclude that, after finitely many flips, no flipping curve can be contained in the boundary.
4.10 Theorem. (Termination of flips for canonical 3-folds) Let $X$ be a normal three dimensional $\mathbb{Q}$-factorial scheme of finite type over a field of characteristic zero and $D$ an effective $\mathbb{Q}$-divisor. Assume that $(X, D)$ is canonical and $\llcorner D\lrcorner=\emptyset$. Then any sequence of flips for $(X, D)$ terminates, i.e., there is no infinite sequence

$$
\begin{array}{cccccc}
\left(X_{0}, D_{0}\right) & \rightarrow\left(X_{1}, D_{1}\right) & \cdots\left(X_{2}, D_{2}\right) & \cdots & \cdots \\
\phi_{0} \searrow & \swarrow \phi_{0}^{+} \phi_{1} \searrow & \swarrow \phi_{1}^{+} \phi_{2} \searrow & \\
Z_{0} & & Z_{1} & & Z_{2}
\end{array}
$$

where $X_{i+1}=\left(X_{i}\right)^{+}$is a $\left(K_{X_{i}}+D_{i}\right)$-flip of $X_{i}$ for each $i$ and $D_{i}$ is the birational transform of $D_{0}=D$.
4.11 Corollary. (Termination of flops for terminal 3-folds) Let $X$ be a normal $\mathbb{Q}$-factorial 3-fold with only terminal singularities and $D$ an effective $\mathbb{Q}$ Cartier divisor. Then any sequence of $D$-flops terminates.
Proof. For $0<\epsilon \ll 1$ the pair $(X, \epsilon D)$ is terminal and any $D$-flop is a $\left(K_{X}+\right.$ $\epsilon D)$-flip.

The proof of (4.10) is done in several steps.

### 4.12 Discrepancy Lemmas.

4.12.1 Lemma. Let $Y$ be a smooth variety with a (not necessarily effective) $\mathbb{Q}$-divisor $B=\sum b_{i} B_{i}$ such tat $\sum B_{i}$ has simple normal crossings.
(4.12.1.1) If $\nu$ is a divisor of $\mathbb{C}(Y)$ then there are $k, n_{i} \in \mathbb{N}$ such that

$$
a_{\ell}(\nu, Y, B)=k+\sum n_{i}\left(1-b_{i}\right)=k+\sum n_{i} a_{\ell}\left(B_{i}, Y, B\right) .
$$

$n_{i}=0$ unless $\operatorname{Center}_{Y}(\nu) \subset B_{i}$ and $k+\sum n_{i} \geq \operatorname{codim}\left(\operatorname{Center}_{Y}(\nu), Y\right)$.
(4.12.1.2) Let $B=E+H=\sum e_{j} E_{j}+\sum h_{k} H_{k}$ such that $e_{j} \leq 1$. Assume that $1-h_{k} \geq c$ for every $k$, where $c$ is some fixed constant with $1 \geq c \geq 0$. Let $\nu$ be a divisor of $\mathbb{C}(Y)$ such that

$$
\#\left\{j \mid \operatorname{Center}_{Y}(\nu) \subset E_{j}\right\}<\operatorname{codim}\left(\operatorname{Center}_{Y}(\nu), Y\right)
$$

Then $a_{\ell}(\nu, Y, E+H) \geq c$.
(4.12.1.3) Assume that $\left(1-b_{k}\right)+\left(1-b_{l}\right) \geq 2$ whenever $B_{k}$ and $B_{l}$ intersect. If $\nu$ is a discrete valuation with small center on $Y$ such that $a_{\ell}(\nu, B)<2$ then $\nu$ is obtained by blowing up the generic point of a subvariety $W \subset Y$ such that $\operatorname{codim}_{Y} W=2$, only one of the $B_{k}\left(\right.$ say $\left.B_{k_{0}}\right)$ contains $W$ and $b_{k_{0}}>0$.

Proof. Let $\nu$ be any discrete valuation of $Y$. Let $Z_{1} \subset Y_{1}=Y$ be the center of $\nu$ on $Y$. Let $Y_{2}$ be the blow up of $Y_{1}$ along $Z_{1}$. Let $Z_{2}$ be the center of $\nu$ on $Y_{2}$. Then $Y_{2}$ is smooth at the generic point of $Z_{2}$ and we can continue the blowing up procedure. After finitely many steps the center of $\nu$ on $Y_{k}$ becomes a divisor. (This is a basic result of Zariski. See [Artin86, 5.2] for a simple self-contained proof.) Thus if we understand the behavior of log discrepancies under a single (smooth) blow up, then we understand them for all discrete valuations.

With this in mind, (4.12.1.1-3) are easy computations. See [Kollár89,3.2] for details.
4.12.2 Lemma. Let $(X, D)$ be a $\log$ variety, where $D=\sum d_{j} D_{j}$ is an effective $\mathbb{Q}$-divisor on $X$. Assume that $(X, D)$ is klt.
(4.12.2.1) There is a finite set of valuations $\left\{\nu_{i}\right\}$ such that if

$$
a_{\ell}(\nu, D)<\min \{2,1+\operatorname{logdiscrep}(X, D)\} \quad \text { and } \quad \nu \notin\left\{\nu_{i}\right\}
$$

then $\nu$ is obtained from blowing up the generic point of a subvariety $W \subset$ $D \subset X$ such that $D$ and $X$ are generically smooth along $W$ (and thus only one of the $D_{j}$ contains $W$ ) and $\operatorname{dim} W=\operatorname{dim} X-2$.
(4.12.2.2) There are only finitely many exceptional divisors $\nu$ such that

$$
a_{\ell}(\nu, D)<\min \left\{1+\log \operatorname{discrep}(X, D), 2-\max _{j}\left\{d_{j}\right\}\right\} .
$$

Proof. The second claim is a consequence of the first. To see the first, take a good resolution $f: Y \rightarrow X$ such that $F=f_{*}^{-1}(D)$ is smooth and let $K_{Y}+\sum h_{k} H_{k} \equiv f^{*}\left(K_{X}+D\right)$. (Thus $F$ is a summand of $\sum h_{k} H_{k}$.) Then $a_{\ell}(\nu, D)=a_{\ell}\left(\nu, \sum h_{k} H_{k}\right)$ for every $\nu$.

We want to change $Y$ so that (4.12.1.3) is satisfied. Assume that it fails for a pair $(k, l)$. Blow up $H_{k} \cap H_{l}$. Let $H^{\prime}$ be the new exceptional divisor. Then

$$
a_{\ell}\left(H^{\prime}, D\right)=a_{\ell}\left(H_{k}, D\right)+a_{\ell}\left(H_{l}, D\right) .
$$

Let $c=\min \left\{1-d_{j}, \operatorname{discrep}(X, D)+1\right\}$. Then

$$
a_{\ell}\left(H^{\prime}, D\right)+a_{\ell}\left(H_{k}, D\right) \geq a_{\ell}\left(H_{k}, D\right)+a_{\ell}\left(H_{l}, D\right)+c .
$$

Repeating this procedure a finite number of times, we can finally achieve that the assumption of (4.12.1.3) is satisfied. By a slight abuse of notation we assume that $f: Y \rightarrow X$ itself satisfies (4.12.1.3).

Thus we obtain (4.12.2.1) except that (4.12.1.3) gives information about the centers on $Y$ and not on $X$.

Assume that $\nu$ is a discrete valuation such that

$$
a_{\ell}(\nu, D)=a_{\ell}\left(\nu, \sum h_{k} H_{k}\right)<2 .
$$

By (4.12.1.3) all but finitely many of these are obtained by blowing up a smooth codimension one point on $\sum H_{k}$. If the center of $\nu$ is contained in $H_{j}$ and $H_{j}$ is $f$-exceptional then

$$
a_{\ell}(\nu, D)=1+a_{\ell}\left(H_{j}, D\right) \geq 1+\log \operatorname{discrep}(X, D) .
$$

Therefore the center of $\nu$ is contained in $F$. Among these $\nu$, there are only finitely many $\nu$ whose center on $X$ does not satisfy (4.12.2.1.1). (The exceptions come from the exceptional divisors of $F \rightarrow D$, the singular locus of $D$ and the singular locus of $X$.)
4.12.3 Definition. Let ( $X, D=\sum d_{j} D_{j}$ ) be a canonical pair. Assume that $\llcorner D\lrcorner=\emptyset$. Fix an integer $N \in \mathbb{N}$ such that $N D$ is a Weil divisor (i.e. $N d_{j} \in \mathbb{N}$ for every $j$ ). Let $d=\max \left\{d_{j}\right\}$. Let

$$
d_{N}(X, D)=\sum_{i=N d}^{\infty} \#\left\{\begin{array}{c}
\text { discrete valuations } \nu \text { with small center on } X \\
\text { such that } a_{\ell}(\nu, D)<2-i / N
\end{array}\right\} .
$$

This is a weighted version of the "difficulty" introduced by [Shokurov85] (see also [Kollár89]). $d_{N}(X, D)<\infty$ by (4.12.2.2).

Shokurov pointed out that even if ( $X, D$ ) is not canonical, $d_{N}(X, D)<\infty$ if $d \geq 1-\log \operatorname{discrep}(X, D)$.
4.12.4 Lemma. Let $(X, D)$ be a canonical pair. Assume that $\llcorner D\lrcorner=\emptyset$. Then $d_{N}(X, D)$ is finite and nonincreasing under flips.

Proof. Let $\nu$ be a discrete valuation with center of codimension $\geq 2$ on $Y$ such that $a_{\ell}(\nu, D)<2$. If $\nu$ is obtained by blowing up a smooth codimension one point of $F_{j}$ then $a_{\ell}(\nu, D)=2-d_{j} \geq 2-d$. Thus finiteness follows from (4.12.2).
(2.28) implies the second part.
(4.13) Proof of (4.10).

Let $(X, D)$ be as in (4.10). Let $D=\sum d_{j} F_{j}$, so $D_{i}=\sum d_{j} F_{j}^{i}$. Consider a sequence of $\left(K_{X}+D\right)$-flips. We prove termination by descending induction on the coefficients $d_{j}$ of $D$, combined with the strategy explained at the beginning of the chapter. As before set $d=\max \left\{d_{j}\right\}(d=0$ if $D=\emptyset)$ and let $G:=$ $\sum_{d_{l}=d} F_{l}$ be the divisor consisting of the $F_{j}$ with the biggest coefficient $(G=$ $X$ if $D=\emptyset$ ). We prove the following two statements:
$(I)_{G}$ After some flips no flipped curve is contained in (the birational transform of) $G$.
$(I I)_{G}$ After some flips no flipping curve is contained in (the birational transform of) $G$.
(Here by a flipping curve we mean any component of a fiber of $\phi_{i}$ and by a flipped curve any component of a fiber of $\phi_{i}^{+}$.)
4.13.1 Subclaim. Suppose a flipped curve $C$ is contained in $G_{i+1}$ (the birational transform of $G$ on $X_{i+1}=X_{i}^{+}$). Let $E_{C}$ be the divisor obtained from blowing up the generic point of $C$. Then there is a $k(C) \in \mathbb{N}$ such that

$$
a_{\ell}\left(E_{C}, D_{i}\right)<a_{\ell}\left(E_{C}, D_{i+1}\right)=2-\frac{k(C)}{N} \leq 2-d
$$

Proof. By (4.9.1) the generic point of $C$ lies in the smooth locus of $X_{i+1}$. By explicit computation

$$
a_{\ell}\left(E_{C}, D_{i+1}\right)=2-\sum m_{j} d_{j}
$$

where $m_{j}$ is the multiplicity of $F_{j}^{i+1}$ along the generic point of $C$. Set $k(C)=$ $N \sum m_{j} d_{j}$. If $C \subset G$ then $k(C) \geq N d$. By (2.23.3)

$$
a_{\ell}\left(E_{C}, D_{i}\right)<a_{\ell}\left(E_{C}, D_{i+1}\right)
$$

4.13.2 Claim. $(I)_{G}$ is true.

Proof. If $\psi_{i}: X_{i} \rightarrow X_{i+1}$ is a flip and a flipped curve is contained in $G$ then by (4.13.1) $d_{N}\left(X_{i+1}, D_{i+1}\right)<d_{N}\left(X_{i}, D_{i}\right)$. Since $d_{N}($,$) is nonnegative, this$ can happen only finitely many times.
4.13.3 Claim. $(I I)_{G}$ is true.

Proof. By virtue of $(I)_{G}$, we may assume that no flipped curve is contained in $G_{i}$. This implies that the induced birational map $\psi_{i}:\left\{G_{i}\right\}^{\nu} \rightarrow\left\{G_{i+1}\right\}^{\nu}$ is actually a morphism, and moreover contracts a curve whenever a flipping curve is contained in $G_{i}$. ( $\left\}^{\nu}\right.$ denotes the normalization.) This cannot be repeated infinitely many times, and thus we have the claim $(I I)_{G}$.

If $D=\emptyset$ then (4.13.2) completes the proof. Otherwise after finitely many flips neither the flipping nor the flipped curve is contained in the birational transform of $G$. In the $\mathbb{Q}$-factorial case this implies that the birational transform of $G$ is disjoint from the flipping curves. Indeed, assume that $C$ intersects $G$ but is not contained in it. Then the $\mathbb{Q}$-factoriality of $X$ implies that there exists a component $G_{0}$ of $G$ such that $C \cdot G_{0}>0$. This in turn implies $C^{+} . G_{0}^{+}<0$ and hence $C^{+} \subset G_{0}^{+} \subset G^{+}$.

Thus we may replace $(X, D)$ by $\left(X \backslash G, \sum_{d_{j}<d} d_{j} F_{j}\right)$ and use induction on the number of irreducible components of $D$.
4.14 Remark. Szabó observed that it is not too difficult to modify the above proof in case $X$ is not $\mathbb{Q}$-factorial. We cannot guarantee that $G$ becomes disjoint from the flipping curves. We need to modify the definition (4.12.3) by counting only those discrete valuations $\nu$ which are not obtained by blowing up the generic point of a curve in $G$. Once neither the flipping nor the flipped curves are contained in $G$, this definition is independent of further flips.

We also need a slight strengthening of (4.10):
4.15 Theorem. Let $X$ be a normal three dimensional $\mathbb{Q}$-factorial scheme of finite type over a field of characteristic zero and $D$ an effective $\mathbb{Q}$-divisor. Assume that $(X, D)$ is canonical. Then any sequence of flips for $(X, D)$ terminates.
Proof. Let $g:(X, D) \rightarrow\left(X^{+}, D^{+}\right)$be a flip and let $C^{+}$be a flipped curve. Assume that $C^{+} \subset\left\llcorner D^{+}\right\lrcorner$. Then by (4.9.1) $X^{+}$is generically smooth along $C^{+}$. Let $E$ be the exceptional divisor obtained by blowing up the generic point of $C^{+}$. Then $0=a\left(E, D^{+}\right)>a(E, D) \geq 0$ gives a contradiction. Thus $C^{+} \not \subset\left\llcorner D^{+}\right\lrcorner$.

As in (4.13.3) we see that after finitely many steps no flipping curve can be contained in $\llcorner D\lrcorner$. Thus after finitely many flips we can replace $X$ by $X \backslash\llcorner D\lrcorner$ and termination is reduced to (4.10).

```
J. KOLLÁR - K. MATSUKI
```

4.15.1 Remark. Shokurov pointed out that the above proof of (4.15) works in positive characteristic as well.

# 5. EXISTENCE OF CANONICAL FLIPS 

Alessio Corti and János Kollár

The aim of this chapter is to prove that if $(X, D)$ is canonical and three dimensional then flips exist. Unfortunately, the proof assumes the existence of flips in the $D=\emptyset$ case, which is a very difficult result of [Mori88]. For technical reasons we need to consider pairs $(X, D)$ which are slightly more general than terminal.
5.1 Definition. We say that the pair ( $X, D$ ) satisfies condition ( $*$ ) if the following assumptions hold:
(5.1.1) $X$ is a normal $\mathbb{Q}$-factorial threefold and $D=\sum d_{i} D_{i}$ is a $\mathbb{Q}$-Cartier divisor; and
(5.1.2) $a(E, D) \geq 0$ for every exceptional divisor $E$ with equality holding only if $E$ is obtained by blowing up (the generic point of) a curve contained in $\llcorner D\lrcorner$.
5.2 Proposition. Assume that ( $X, D$ ) satisfies (*). If ( $X^{\prime}, D^{\prime}$ ) is obtained from ( $X, D$ ) by a sequence of $D$-flips or extremal contractions which do not contract any components of $D$, then ( $X^{\prime}, D^{\prime}$ ) also satisfies (*).

Proof. It is sufficient to consider one flip or contraction $g: X \rightarrow X^{\prime}$. Let $C^{\prime} \subset X^{\prime}$ be the exceptional set of $g^{-1}$. If $E$ is an exceptional divisor over $X^{\prime}$ such that $\operatorname{Center}_{X^{\prime}}(E) \not \subset C^{\prime}$ then $a\left(E, D^{\prime}\right)=a(E, D)$. Thus assume that Center $_{X^{\prime}}(E) \subset C^{\prime}$. In this case, $a\left(E, D^{\prime}\right)>a(E, D)$ by (2.23.3) and (2.28.3).

The only case that needs attention is when $g$ is a divisorial contraction and $E$ the exceptional divisor of $g$ (since $E$ is not exceptional over $X$ ). If $E$ is not a component of $D$ then $a(E, D)=0$. Otherwise $a(E, D)<0$, hence $E \subset \operatorname{Supp} D$, which was excluded.
5.3 Lemma. Assume ( $X, D$ ) satisfies (*). Then
(5.3.1) $X$ has terminal singularities;
(5.3.2) If $x \in\llcorner D\lrcorner$ then $X$ and $D$ are smooth at $x$.

Proof. The first part is clear.

The second part can be done by hand, but it is easier to use adjunction. Assume that $x \in\llcorner D\lrcorner$. Pick a component $S \subset\llcorner D\lrcorner$ containing $x$. By (17.2) $(S, \operatorname{Diff}(D-S))$ is terminal, and thus by (4.9.1) $S$ is smooth. Let $p:\left(x^{\prime}, X^{\prime}\right) \rightarrow(x, X)$ be the index one cover in a neighborhood of $x$. The covering is étale outside $x$ and has degree equal to index $(x \in X)$. $S$ is smooth, thus $p^{-1}(S)$ is a union of index $(x \in X)$ irreducible components intersecting at $x^{\prime} . p^{-1}(S)$ is a $\mathbb{Q}$-Cartier divisor on the cDV variety $X^{\prime}$, thus Cartier by (6.7.2). Therefore $p^{-1}(S)$ is $S_{2}$. Let $i: U=p^{-1}(S)-\left\{x^{\prime}\right\} \rightarrow p^{-1}(S)$ be the injection. Since $p^{-1}(S)$ is $S_{2}, i_{*} \mathcal{O}_{U} \cong \mathcal{O}_{p^{-1}(S)}$. This implies that $p^{-1}(S)$ is irreducible. Therefore index $(x \in X)=1, X$ is a cDV point and $S$ is Cartier. Hence $X$ is also smooth.
5.4 Theorem. Assume that $(X, D)$ is canonical. Let $f: X \rightarrow Z$ be a small extremal contraction such that $-\left(K_{X}+D\right)$ is $f$-ample and $\rho(X / Z)=1$. Then the flip of $f$ exists.

Proof. The proof is in two steps. First we establish the result in the case when $D$ is reduced and satisfies (*). Then we prove the general case by induction on the number of irreducible components of $D$.
5.4.1 Step 1. (5.4) holds if $D=\sum D_{i}$ is reduced and satisfies (*).

Let $C \subset X$ be the exceptional curve. By shrinking $Z$, we may assume that $C$ is connected. If $C \cdot D_{i} \geq 0$ then we can discard $D_{i}$. If we discard all the $D_{j}$ then $C \cdot K_{X}<0$. Then the flip exists by [Mori88] (the flips with respect to $K_{X}+D$ and with respect to $K_{X}$ coincide, cf. (2.32.1)).

If we assume that $C \cdot D_{1}<0$, then $C \subset D_{1}$. Thus no other component of $D$ intersects $C$ by (5.3.2) and $S=D_{1}$ is smooth along $C$. Consider the contraction $f: S \rightarrow f(S)$. $K_{S}=K+S \mid S$. Thus $-K_{S}$ is $(f \mid S)$-ample. Therefore $f \mid S$ is the contraction of a single -1-curve $C$ and $(K+S) \cdot C=-1$.

Suppose that $S \cdot C=-m$, so that $K \cdot C=m-1$. Furthermore,

$$
\mathcal{O}_{X}(K+S)^{\otimes m} \cong \mathcal{O}_{X}(D),
$$

at least in a neighborhood of $C$. Using the natural section of $\mathcal{O}_{X}(S)$ we can construct a degree $m$ cyclic cover $p: X^{m} \rightarrow X$ ramified along $S$. Let $Z^{m}$ be the normalization of $Z$ in $X^{m}$ and $f^{m}: X^{m} \rightarrow Z^{m}$ the induced contraction of $C^{m}=p^{-1}(C)$. By the ramification formula

$$
C^{m} \cdot K_{X^{m}}=C^{m} \cdot p^{*}\left(K_{X}+\frac{m-1}{m} S\right)=C \cdot K_{X}+\frac{m-1}{m} C \cdot S=0
$$

Therefore $f^{m}$ is a flopping contraction and the opposite $\left(X^{m}\right)^{+} \rightarrow Z^{m}$ exists by (4.8). Thus $X^{+}=\left(X^{m}\right)^{+} / \mathbb{Z}_{m}$ is the tlip of $f$.
5.4.2 Step 2. We prove (5.4) by induction on the number of irreducible components of $D=\sum d_{i} D_{i}$.

By (2.32.1) we may assume that $\llcorner D\lrcorner=\emptyset$ and by (2.29) it is sufficient to construct a model

$$
X \xrightarrow{\phi} \bar{X} \xrightarrow{\bar{f}} Z
$$

such that $K_{\bar{X}}+\phi_{*}(D)$ is $\bar{f}$-nef.
(5.4.2.1) Let $g: X^{\prime} \rightarrow X \rightarrow Z$ be a $\log$ resolution of $(X, D)$ such that Supp $g_{*}^{-1}(D)$ is smooth. By construction $\left(X^{\prime},\left\ulcorner g_{*}^{-1}(D)\right\urcorner\right)$ satisfies $(*)$. We apply the $\left(K+\left\ulcorner g_{*}^{-1}(D)\right\urcorner\right)$-MMP to $g: X^{\prime} \rightarrow Z$. Note that $g$ is birational on $\left\ulcorner g_{*}^{-1}(D)\right\urcorner$. Therefore we never have to contract a component of $\left\ulcorner g_{*}^{-1}(D)\right\urcorner$. Thus all flips exist by Step 1, and the program terminates by (4.15). At the end we obtain

$$
\left(X^{\prime},\left\ulcorner g_{*}^{-1}(D)\right\urcorner\right) \xrightarrow{\psi}(Y, B) \xrightarrow{h} Z,
$$

where $B=\sum B_{i}=\left\ulcorner h_{*}^{-1}(D)\right\urcorner$ and $K_{Y}+B$ is $h$-nef and satisfies (*).
(5.4.2.2) The aim is now to shrink $B$ down to $h_{*}^{-1}(f(D))$. For notational simplicity we not distinguish $D$ and $f(D)$; this does not lead to any confusion. Assume that we already constructed

$$
h^{j}:\left(Y^{j}, B^{j}\right) \rightarrow Z \quad \text { where } \quad B^{j}=\sum_{i<j} d_{i}\left(h^{j}\right)_{*}^{-1}\left(D_{i}\right)+\sum_{i \geq j}\left(h^{j}\right)_{*}^{-1}\left(D_{i}\right),
$$

such that $K+B^{j}$ is $h^{j}$-nef and satisfies (*). In (5.4.2.1) we constructed $(Y, B)=\left(Y^{1}, B^{1}\right)$.
(5.4.2.3) Our next goal is to construct $\left(Y^{j+1}, B^{j+1}\right)$. For notational simplicity we drop the upper index $j$ from the notation and write $(Y, B)$ instead of $\left(Y^{j}, B^{j}\right)$ etc.

By definition $K+B$ is $h$-nef. Consider the largest $0 \leq \epsilon \leq 1-d_{j}$ such that $K+B-\epsilon B_{j}$ is $h$-nef. If $\epsilon=1-d_{j}$ then

$$
K+\sum_{i<j+1} d_{i} h_{*}^{-1}\left(D_{i}\right)+\sum_{i \geq j+1} h_{*}^{-1}\left(D_{i}\right)
$$

is $h$-nef and we can take $Y^{j+1}=Y^{j}$.
Otherwise we try to increase $\epsilon$ as follows. Take $0<\eta \ll \epsilon$. Then

$$
K+B-(\epsilon+\eta) B_{j}
$$

is not nef. We can apply the $\left(K+B-(\epsilon+\eta) B_{j}\right)$-MMP. We successively construct the objects

$$
\left(h_{i}: Y_{i} \rightarrow Z, K+B-(\epsilon+\eta) B_{j}\right) .
$$

By (2.35) for fixed $\eta$ there are only finitely many $\left(K+B-(\epsilon+\eta) B_{j}\right)$-extremal rays. Thus we may assume that if $R$ generates a $\left(K+B-(\epsilon+\eta) B_{j}\right)$-extremal ray then

$$
R \cdot\left(K+B-\epsilon B_{j}\right)=0
$$

Therefore, if $C_{i}$ is a flipping curve, then

$$
\begin{equation*}
\left(K+B-(\epsilon+\eta) B_{j}\right) \cdot C_{i}=-\eta B_{j} \cdot C_{i}<0 \tag{5.4.2.4}
\end{equation*}
$$

Set

$$
B^{\prime}=\sum_{i<j} d_{i} h_{*}^{-1}\left(D_{i}\right)+\sum_{i \geq j+1} h_{*}^{-1}\left(D_{i}\right)
$$

From (5.4.2.4) we conclude that

$$
B_{j} \cdot C_{i}>0 \quad \text { and } \quad\left(K+B^{\prime}\right) \cdot C_{i}<0
$$

Thus the flip required is also a $\left(K+B^{\prime}\right)$-flip, which exists by induction since $B^{\prime}$ has one fewer irreducible components. After some flips and contractions we can increase the value of $\epsilon$ to $\epsilon^{\prime} \geq \epsilon+\eta$. Next apply the $\left.\left(K+B-\left(\epsilon^{\prime}+\eta^{\prime}\right) B_{j}\right)\right)$ MMP, and so on.

We claim that after finitely many steps we reach $\epsilon=1-d_{j}$. As usual, the only question is the termination of flips. As was remarked above, every flip is a $\left(K+B^{\prime}\right)$-flip, and so termination follows from (4.15). In the end we obtain

$$
h^{j+1}:\left(Y^{j+1}, B^{j+1}\right) \rightarrow Z
$$

(5.4.2.5) If $D$ has $k$ components then iterating (5.4.2.3) we obtain

$$
h^{k+1}:\left(Y^{k+1}, B^{k+1}\right) \rightarrow Z \quad \text { such that } \quad B^{k+1}=\left(h^{k+1}\right)_{*}^{-1}(D)
$$

Thus we can take $\bar{X}=X^{k+1}$.
5.5 Remark. One can consider the $(K+D)$-MMP for terminal or canonical pairs. In general it can occur that an extremal contraction creates a pair $\left(X^{\prime}, D^{\prime}\right)$ which is not canonical. This can happen when we contract an irreducible component of $D$. There are some geometric conditions which ensure that this does not occur.

The simplest case is when we do the relative MMP with respect to a morphism $f: X \rightarrow Y$ such that $f$ is generically finite on every irreducible component of $D$. Another example is when $D$ is reduced and every irreducible component has nonnegative Kodaira dimension.

Assume that we avoid the above problem and the $(K+D)$-MMP terminates with a pair $\left(X^{m}, D^{m}\right)$ such that $K+D^{m}$ is nef and satisfies (*). In general
$X^{m}$ is not unique in codimension one since we can always blow up a smooth curve inside the smooth locus of $\left\llcorner D^{m}\right\lrcorner$ to obtain another minimal model. In order to remedy the situation we introduce the following notion:
5.6 Definition. We say that a pair $\left(X^{\prime}, D^{\prime}\right)$ is a $\left(K+(1-0) D^{\prime}\right)$-minimal model if the following conditions are satisfied:
(5.6.1) $\left(X^{\prime}, D^{\prime}\right)$ is canonical;
(5.6.2) $\left(X^{\prime}, D^{\prime}\right)$ is terminal outside $\left\ulcorner D^{\prime}\right.$ (equivalently, $X^{\prime}$ has terminal singularities);
(5.6.3) $K+(1-\epsilon) D^{\prime}$ is nef for every $0 \leq \epsilon \ll 1$.
5.7 Construction. Assume that $(X, D)$ satisfies $(*)$. The construction of $(K+$ $(1-0) D)$-minimal models proceeds along the lines of the MMP. First we apply the $(K+D)$-MMP. Thus eventually we obtain $\left(X^{m}, D^{m}\right)$, unless we run into a forbidden contraction as in (5.5).

If $K+(1-\epsilon) D^{m}$ is nef for some $0<\epsilon$ then we can take $X^{\prime}=X^{m}$. Otherwise, we choose $\epsilon$ such that every $\left(K+(1-\epsilon) D^{m}\right)$-extremal ray $R$ has zero intersection with $K+D^{m}$ and apply the $\left(K+(1-\epsilon) D^{m}\right)$-MMP.

Assume that we need to flip a curve $C \subset X^{m}$. Then

$$
\left(K+(1-\epsilon) D^{m}\right) \cdot C=-\epsilon D^{m} \cdot C<0
$$

and therefore $(1-\epsilon) D^{m} \cdot C>0$ and $K \cdot C<0$. Thus every such $\log$ flip is a $K$-flip. Hence they exist by [Mori88] and any sequence terminates. Of course again there is the possibility that we contract a component of $D$.

These models have the same uniqueness property as ordinary minimal models:
5.8 Proposition. Assume that $(X, D)$ satifies $(*)$ and let $\left(X^{i}, D^{i}\right)(i=1,2)$ be two $(K+(1-0) D)$-minimal models. Then the natural birational map $X^{1} \rightarrow X^{2}$ is an isomorphism in codimension one.

Proof. Choose $\epsilon$ so that $K+(1-\epsilon) D^{i}$ is nef for $i=1,2$. Then $\left(X^{i},(1-\epsilon) D^{i}\right)$ are terminal. The rest of the proof is essentially the same as in [Kollár89,4.3]. We do not use this result in the rest of the notes.
5.9 Remark. It is interesting to note that the above notions can be used to unify flops, flips and inverses of flips. Consider pairs ( $X, D$ ) with $D$ reduced which are canonical and terminal outside $D$. The flops in this category are precisely the following:
terminal flops ( $D$ is a member of $\left|\mathcal{O}_{X}\right|=\left|-K_{X}\right|$ );
terminal flips ( $D$ is a member of $\left|-K_{X}\right|$, [Kollár-Mori92, 1.7]); and inverses of terminal flips ( $D$ is a member of $\left|-K_{X}\right|$, [Kollár-Mori92, Ch.3]).

## 6. CREPANT DESCENT

JÁnos Kollár

The aim of this chapter is to develop a reduction method for $\log$ flips. The main results say that if $f: Y \rightarrow X$ is a birational morphism such that $K_{Y} \equiv f^{*} K_{X}$ (i.e. $f$ is crepant) then flipping on $X$ can be reduced to flipping on $Y$. This method first appeared in [Kawamata88] and was further developed in [Kollár89] and [Kawamata91c]. First we outline the general method of doing this, called the Backtracking Method. Then we prove the two main applications in (6.10-11).

We start with three auxiliary lemmas.
6.1 Lemma. Let $h: U \rightarrow Z$ be a projective morphism such that $h_{*} \mathcal{O}_{U}=\mathcal{O}_{Z}$. Assume that $\rho(U / Z)=2$. Then there are at most two normal and projective schemes $V_{j} \rightarrow Z(j=1,2)$ giving nontrivial factorizations

$$
U \rightarrow V_{j} \rightarrow Z
$$

such that $U \rightarrow V_{j}$ has connected fibers.
Proof. Let $H_{j}$ be ample on $V_{j} / Z$ and let $M_{j}$ be the pull-back of $H_{j}$ to $U$. Then $M_{j}$ is nef and trivial on the curves that are contained in the fibers of $U \rightarrow V_{j}$.

$$
\left\{[D] \mid D \cdot M_{j}=0\right\} \subset \overline{N E}(U / Z) \subset \mathbb{R}^{2}
$$

is an extremal face which determines $V_{j}$. A convex cone in $\mathbb{R}^{2}$ has only two edges, thus there can be at most two contraction morphisms $U \rightarrow V_{j}$.
6.2 Lemma. Let $Y$ be a normal $\mathbb{Q}$-factorial variety. Let $q: Y \rightarrow X$ be a projective birational morphism such that $\rho(Y / X)=1$. Let $q^{\prime}: Y^{\prime} \rightarrow X$ be another projective birational morphism with a unique exceptional divisor $E^{\prime} \subset Y^{\prime}$. Assume that the composite birational map $q^{-1} \circ q^{\prime}: Y^{\prime} \rightarrow Y$ is an isomorphism at the generic point of $E^{\prime}$. Then $q^{-1} \circ q^{\prime}$ is an isomorphism.
Proof. Let $H^{\prime}$ be an effective, irreducible $q^{\prime}$-ample divisor. Its birational transform $H$ on $Y$ is an irreducible and effective divisor which does not contain the
S. M. F.
exceptional set of $q$. Since $\rho(Y / X)=1$, this implies that $H$ is $q$-ample. Thus $q^{-1} \circ q^{\prime}$ is an isomorphism in codimension one and transforms the $q^{\prime}$-ample divisor $H^{\prime}$ into the $q$-ample divisor $H$. This easily implies that $q^{-1} \circ q^{\prime}$ is an isomorphism.
6.3 Lemma. Let $g: Y \rightarrow Z$ and $g^{\prime}: Y^{\prime} \rightarrow Z$ be proper birational morphisms. Let $\phi: Y \rightarrow Y^{\prime}$ be a $Z$-map, isomorphic in codimension one. Let $H$ be a divisor on $Y$ and let $H^{\prime}=\phi(H)$. Assume that both $H$ and $H^{\prime}$ are $\mathbb{Q}$-Cartier. If $-H$ is $g$-ample and $H^{\prime}$ is $g^{\prime}$-nef then $g$ and $g^{\prime}$ are both small.

Proof. Let $F^{\prime} \subset Y^{\prime}$ be the closed subset where $\phi^{-1}$ is not an ismorphism. For $m \gg 1,|-m H|$ is $g$-very ample, hence base point free. Thus $\phi_{*}|-m H|$ is base point free outside $F^{\prime}$. If $g^{\prime}: Y^{\prime}-F^{\prime} \rightarrow Z$ is not an immersion then there is a proper curve $C^{\prime} \subset Y^{\prime}$ such that $g^{\prime}\left(C^{\prime}\right)=$ point, $C^{\prime}$ intersects $F^{\prime}$ but is not contained in it. Thus $C^{\prime} \cdot\left(-H^{\prime}\right)>0$, a contradiction.

### 6.4 Backtracking Method.

Let $f: X \rightarrow Z$ be a small contraction with $\rho(X / Z)=1$ and let $H$ be a $\mathbb{Q}$-Cartier divisor on $X$ such that $-H$ is $f$-ample. The aim of the method is to construct the opposite of $f$ with respect to $H$.

Set $X=X_{0}$. As a first step we construct a birational projective morphism $q_{1}: Y_{1} \rightarrow X_{0}$ such that $\rho\left(Y_{1} / X\right)=1$ and $\rho\left(Y_{1} / Z\right)=2$. (The latter is automatic if $X$ is $\mathbb{Q}$-factorial.) If $X_{0}$ is $\mathbb{Q}$-factorial, this implies that the exceptional set of $q_{1}$ is an irreducible divisor.

Assume that $q_{i}: Y_{i} \rightarrow X_{i-1} \rightarrow Z$ is already constructed. By (6.1) there are at most two nontrivial factorizations

$$
Y_{i} \rightarrow V_{j} \rightarrow Z
$$

$X_{i-1}$ is one of them. The corresponding extremal ray is denoted by $Q_{i}$. Let $R_{i}$ be the other extremal ray and let $r_{i}: Y_{i} \rightarrow X_{i}$ be the corresponding contraction (provided it exists). If $r_{i}$ is a divisorial contraction, we stop. Our hope is that $X_{i}$ is the opposite of $X \rightarrow Z$. If $r_{i}$ is a small contraction then let $q_{i+1}: Y_{i+1} \rightarrow X_{i}$ be the opposite (if it exists).

We have to be a little more careful if $Y_{1} \rightarrow Z$ is small. (This never happens in most applications.) In this case we stop the method when the birational transform of $-q_{1}^{*} H$ becomes nef on $Y_{i}$. If it becomes ample then $Y_{i} \rightarrow Z$ is the flip of $X_{0} \rightarrow Z$. Otherwise $-q_{1}^{*} H$ should descend to $X_{i}$, thus $X_{i} \rightarrow Z$ is the required flip.

In working with the method we always use the above notation. Also, if $D$ is a divisor on $X$ or on $Y_{1}$, its birational transform on $Y_{i}$ is denoted by $D_{i}$. We usually write simply $K$ instead of $K_{Y_{i}}$ or $K_{X}$ if no confusion is likely.

Thus starting with $q_{1}: Y_{1} \rightarrow X_{0}$ we define a unique chain of projective $Z$-schemes and morphisms:

The necessary steps for the success of this approach are the following:
(6.4.1) The construction of $q_{1}: Y_{1} \rightarrow X_{0}$ (mostly easy).
(6.4.2) Proof that the contractions $r_{i}$ exist (easy).
(6.4.3) Proof that the opposites $q_{i+1}: Y_{i+1} \rightarrow X_{i}$ exist (this is the hardest).
(6.4.4) Proof that eventually we get a divisorial contraction $r_{j}: Y_{j} \rightarrow X_{j}$ (easy using Chapters 4 and 7).
(6.4.5) Proof that $X_{j} \rightarrow Z$ is indeed the opposite of $X \rightarrow Z$ (easy).

It is convenient to imagine the bactracking method by drawing a picture of the ample cones. By assumption there are natural isomorphism

$$
N^{1}\left(Y_{1}\right) \cong N^{1}\left(Y_{2}\right) \cong \ldots \xlongequal{\text { def }} N^{1} \cong \mathbb{R}^{2} .
$$

For each $i$, let Amp $Y_{i} \subset N^{1}$ be the closed cone generated by the relatively ample divisors of $Y_{i} / Z$. The two edges of the cone $\operatorname{Amp} Y_{i}$ correspond to the two contractions $q_{i}$ and $r_{i}$ : they are given by pull backs of ample divisors from $X_{i-1}$ and from $X_{i}$. In particular, the cones Amp $Y_{i}$ and Amp $Y_{i+1}$ share a common edge corresponding to the pull back of ample divisors from $X_{i}$. Thus we obtain a subdivision of $N^{1}$ into a collection of cones.

6.4.6 Lemma. Notation as above. All the cones Amp $Y_{i}$ are in one of the half planes determined by the line $\mathbb{R}\left[q_{1}^{*} H\right]$. In particular, all the cones Amp $Y_{i}$ are different, hence $Y_{i}$ and $Y_{j}$ are not isomorphic over $Z$ if $i \neq j$.

Proof. The shaded area represents those divisors $F$ for which $-F$ is ample on $Y_{1}$. Thus if $Y_{1} \rightarrow Z$ is not small then by (6.3) the cones Amp $Y_{m}$ are disjoint from the shaded area. If $Y_{1} \rightarrow Z$ is small then we stop the method when $q_{1}^{*} H$ becomes nef. Thus in both cases we stay in the halfplane containing $\operatorname{Amp} Y_{1}$.

### 6.5 General Properties of the Backtracking Method.

6.5.1. When applying the Backtracking Method, the choice of $q_{1}: Y_{1} \rightarrow X_{0}$ is our only freedom. In some cases it is easy, in some other cases it is fairly hard to prove that a choice with very good properties exists.
6.5.2 Claim. Notation as above. Assume that $-D_{1}$ is relatively ample on $Y_{1} / Z$. Then the steps of the Backtracking Method are steps of the $D_{1}-M M P$ applied to $\left(Y_{1}, D_{1}\right)$.

Proof. We assumed the $i=1$ case. By induction assume next that this holds for $i$. Thus $D_{i} \cdot R_{i}<0$. Then $D_{i+1} \cdot Q_{i+1}>0$. If $Y_{1} \rightarrow Z$ is not small, then by (6.3) $D_{i+1}$ is not nef on $Y_{i+1}$, thus $D_{i+1} \cdot R_{i+1}<0$.

If $Y_{1} \rightarrow Z$ is small, then it can happen that $D_{i+1}$ is nef on $Y_{i+1}$. This however was declared to be the last step of the method.
6.5.2.1 Complement. Notation as above. Assume that $X_{0}$ is $\mathbb{Q}$-factorial and $H=K+\Delta$ where $\left(X_{0}, \Delta\right)$ is klt. Let $E_{1} \subset Y_{1}$ be the exceptional divisor. Then $D_{1}=K+\Delta_{1} \xlongequal{\text { def }} q_{1}^{*}(K+\Delta)+\epsilon E_{1}$ is klt and negative on $Y_{1} / Z$ for $0<\epsilon \ll 1$. Therefore the steps of the backtracking method become the steps of the $\left(K+\Delta_{1}\right)$-MMP. In particular the contractions $r_{i}$ exist.
6.5.3. In the general framework I cannot say anything about the existence of the opposites. In the applications the crucial point is to show that the singularities of $Y_{i}$ are "simpler" than the singularities of $X_{0}$. Thus we prove existence of flips by reduction to "simpler" singularities. Unfortunately the notions of "simplicity" used seem rather artificial and it is not clear how to generalize them to higher dimensions.
6.5.4. Termination of flips is again a problem. In the applications the results of Chapters 4 and 7 imply that eventually we get a divisorial contraction $r_{m}: Y_{m} \rightarrow X_{m}$.
6.5.5 Proposition. Notation and assumptions as above. Assume furthermore that $X$ and $Y_{1}$ are $\mathbb{Q}$-factorial. Assume that eventually we get a divisorial contraction $r_{m}: Y_{m} \rightarrow X_{m}$. Then $X_{m} \rightarrow Z$ is the opposite of $X \rightarrow Z$.

Proof. By (4.5), if $X$ is $\mathbb{Q}$-factorial then $Z$ has at most two small modifications, $X$ and its opposite. Therefore it is sufficient to show that

$$
\psi: X \rightarrow Z \leftarrow X_{m}
$$

is not an isomorphism. (Warning! It can easily happen that $X$ and $X_{m}$ are isomorphic as varieties, but they are not isomorphic over $Z$.)

Assume the contrary. Then

$$
\phi: Y_{1} \xrightarrow{q_{1}} X \cong X_{m} \stackrel{r_{m}}{\longleftrightarrow} Y_{m}
$$

is also an isomorphism by (6.2). This is however impossible by (6.4.6).
Next we formulate the crepant descent theorems. First we collect properties of flops and terminal flips of threefolds that are needed during the proof of the descent theorems. The lists are complete in the sense that if (6.7) (resp. (6.9)) holds in dimension $n$ then (6.10) (resp. (6.11)) also holds in dimension $n$. (Unfortunately, as Matsuki pointed out to me, (6.7.2) has no analog in dimension $\geq 4$.)
6.6 Definition. Let $(X, B)$ be a klt threefold. By (4.12.1) there are only finitely many exceptional divisors (i.e. valuations) with $\log$ discrepancy $\leq 1$. The number of these divisors is denoted by $e(X, B)$. If $B=\emptyset$, then we write $e(X)$. Thus $(X, B)$ is terminal (4.9) iff $e(X, B)=0$.
6.7 Proposition. Let $Y$ be a threefold with terminal singularities.
(6.7.1) Flops exist and terminate with respect to any effective Cartier divisor.
(6.7.2) Let $E$ be a $\mathbb{Q}$-Cartier Weil divisor on $Y$. Then index $(Y) E$ is Cartier.
(6.7.3) The index is unchanged under flops.
(6.7.4) [Reid80,83] Let $X$ be a threefold with canonical singularities. Then there is a threefold with $\mathbb{Q}$-factorial terminal singularities $Y$ and a projective morphism $f: Y \rightarrow X$ such that $K_{Y} \equiv f^{*} K_{X}$.
Proof. (6.7.1) was proved in Chapter 4.
(6.7.2) follows from the following local result (in the analytic topology): if $D$ is $\mathbb{Q}$-Cartier then index $(0 \in Y) D$ is Cartier. To prove this let $p: Y^{\prime} \rightarrow Y$ be the index one cover. Then $p_{*} p^{*} D=\operatorname{index}(0 \in Y) D$, thus it is sufficient to consider the index one case. An index one terminal singularity is a hypersurface in $\mathbb{C}^{4}$. Therefore $Y^{\prime}-\{0\}$ is simply connected (see e.g. [Milnor68]), and thus $H^{2}\left(Y^{\prime}-\{0\}, \mathbb{Z}\right)$ is torsion free. Therefore any $\mathbb{Q}$-Cartier divisor is Cartier.

Let $X \xrightarrow{f} Z \stackrel{f^{+}}{\longleftarrow} X^{+}$be a flop. Then by the Base Point Free Theorem $[\operatorname{KMM} 87,3-1-1] \operatorname{index}(X)=\operatorname{index}(Z)=\operatorname{index}\left(X^{+}\right)$which proves (6.7.3).

## J. KOLLÁR

(6.7.4) is the most difficult. First, by [Reid80] (cf. [CKM88,6.19-25]) there is a morphism $g^{\prime}: Y^{\prime} \rightarrow X$ such that $K_{Y^{\prime}} \equiv g^{\prime *} K_{X}$ and $Y^{\prime}$ has only terminal singularities. Thus it is sufficient to prove the exsitence of a small morphism $Y \rightarrow Y^{\prime}$ such that $Y$ is $\mathbb{Q}$-factorial and terminal. (We could just resolve $Y^{\prime}$ and run the MMP. However, it is desirable to give a proof which uses less.)

In order to prove this we first note the easy result that $\mathrm{Weil}\left(Y^{\prime}\right) / \operatorname{Pic}\left(Y^{\prime}\right)$ is finitely generated since $Y^{\prime}$ has rational singularities (see (16.3.1) for the definition of Weil). Let $D \in \operatorname{Weil}\left(Y^{\prime}\right) / \operatorname{Pic}\left(Y^{\prime}\right)$ be a nontorsion element. By (4.7) there is a small morphism $Y_{1}^{\prime} \rightarrow Y^{\prime}$ such that the birational transform $D_{1}$ of $D$ is torsion of order $m_{1}$ in $\operatorname{Weil}\left(Y_{1}^{\prime}\right) / \operatorname{Pic}\left(Y_{1}^{\prime}\right)$. Since

$$
\operatorname{Weil}\left(Y_{1}^{\prime}\right)=\operatorname{Weil}\left(Y^{\prime}\right) \quad \text { and } \quad \operatorname{Pic}\left(Y_{1}^{\prime}\right) \supset\left\langle\operatorname{Pic}\left(Y^{\prime}\right), m_{1} D_{1}\right\rangle
$$

we see that

$$
\operatorname{rank}_{\mathbb{Z}} \mathrm{Weil}\left(Y_{1}^{\prime}\right) / \operatorname{Pic}\left(Y_{1}^{\prime}\right) \leq \operatorname{rank}_{\mathbb{Z}} \mathrm{Weil}\left(Y^{\prime}\right) / \operatorname{Pic}\left(Y^{\prime}\right)-1
$$

Therefore after finitely many steps we obtain a small projective morphism $Y=Y_{m}^{\prime} \rightarrow Y^{\prime}$ such that $Y$ is $\mathbb{Q}$-factorial.
6.8 Definition. Let $(X, B)$ be an lc threefold. Let $H$ be a Cartier divisor on $X$. Let $f: X \rightarrow Z$ be a small contraction such that $K_{X}+B$ is numerically $f$-trivial and $-H$ is $f$-ample. The opposite of $f$ with respect to $H$ is called an $H$-flop with respect to $K+B$ or simply an $H$-flop. If $(X, B)$ is klt then $(X, B+\epsilon H)$ is klt for $0<\epsilon \ll 1$ and an $H$-flop is a $(K+B+\epsilon H)$-log flip.
6.9 Proposition. Let $(Y, D)$ be a terminal threefold.
(6.9.1.1) $H$-flops exist and terminate with respect to any effective Cartier divisor $H$.
(6.9.1.2) Terminal flips exist and terminate.
(6.9.2) [Kawamata91c] Set $r(Y, D)=\left(4\left\ulcorner\operatorname{discrep}(Y, D)^{-1}\right\urcorner\right)$ !. Let $E$ be a $\mathbb{Q}$-Cartier Weil divisor on $Y$. (Assume for simplicity that $K_{Y}$ is $\mathbb{Q}$-Cartier.) Then $r(Y, D) E$ is Cartier.
(6.9.3) Let $(X, B)$ be a klt threefold. discrep $(X, B)$ is nondecreasing under flops and flips.
(6.9.4) [Kawamata91c] Let $(X, B)$ be a klt threefold. Then there is a terminal threefold $(Y, D)$ with $\mathbb{Q}$-factorial singularities and a projective morphism $f: Y \rightarrow X$ such that $f_{*} D=B$ and $K_{Y}+D \equiv f^{*}\left(K_{X}+B\right)$.

Proof. (6.9.1.1) was proved in Chapter 4.
(6.9.1.2) was proved in Chapters 4 and 5.
(6.9.2) can be proved as follows. Let $y \in Y$ be a singular point. Then $y \in Y$ is terminal. Let $r$ be its index. By (6.7.2) $r E$ is Cartier at $y$. We see
in (6.9.7) that there is an exceptional divisor $E_{y}$ dominating $y$ such that

$$
\frac{4}{r} \geq a\left(E_{y}, \emptyset\right) \geq a\left(E_{y}, D\right) \geq \operatorname{discrep}(Y, D)
$$

Thus $r$ divides $r(Y, D)$, and hence $r(Y, D) E$ is Cartier at $y$.
(6.9.3) is a special case of (2.28) and holds in all dimensions.

Finally consider (6.9.4). Let $h_{0}: V_{0} \rightarrow X$ be a $\log$ resolution such that:
(6.9.5.1) If $\nu_{j}$ is a discrete rank one valuation with $\log$ discrepancy at most one, then $E_{j}=$ Center $_{V_{0}}\left(\nu_{j}\right)$ is a divisor;
(6.9.5.2) $\cup E_{j} \cup($ birational transform of $B)$ has smooth support (i.e. different components are disjoint).

We write

$$
K_{V_{0}} \equiv h_{0}^{*}\left(K_{X}+B\right)+E^{+}-E^{-}
$$

where $E^{+}, E^{-}$are effective $\mathbb{Q}$-divisors without common components. By (6.9.5.2) $\operatorname{Supp} E^{-}$is smooth. Therefore $K_{V_{0}}+E^{-}$is terminal.

Apply the $\left(K_{V_{0}}+E^{-}\right)$-minimal model program to $V_{0} / X$. Assume that we have already constructed $V_{0} \xrightarrow{r_{i}} V_{i} \xrightarrow{h_{i}} X$ and the birational transform $E_{i}^{-}=\left(r_{i}\right)_{*} E^{-}$such that
(6.9.6.1) $r_{i}$ does not contract any irreducible components of $E^{-}$; and
(6.9.6.2) $K_{V_{i}}+E_{i}^{-}$is terminal.

Let $p_{i}: V_{i} \rightarrow Z_{i}$ be the contraction of a $\left(K_{V_{i}}+E_{i}^{-}\right)$-extremal ray. If $p_{i}$ is small, the flip exists by (6.9.1.2). Assume that $p_{i}$ is divisorial with exceptional divisor $F_{i}$.

$$
K_{V_{i}}+E_{i}^{-}=h_{i}^{*}\left(K_{X}+B\right)+\left(r_{i}\right)_{*} E^{+}
$$

and $F_{i} \subset \operatorname{Supp}\left(r_{i}\right)_{*} E^{+}$. Hence $r_{i+1}=p_{i} \circ r_{i}$ satisfies (6.9.6.1) and this implies (6.9.6.2) for $i+1$. Thus eventually we obtain $h_{m}: V_{m} \rightarrow X$ such that

$$
K_{V_{m}}+E_{m}^{-} \equiv h_{m}^{*}\left(K_{X}+B\right)+\left(r_{m}\right)_{*} E^{+} \quad \text { is } h_{m} \text {-nef. }
$$

Therefore $\left(r_{m}\right)_{*} E^{+}=\emptyset$. Set $(Y, D)=\left(V_{m}, E_{m}^{-}\right)$.
It is quite likely that one can prove (6.9.4) by explicit blow ups as is the case for (6.7.4).
6.9.7 Lemma. (Kawamata in appendix to [Shokurov91]) Let $(0 \in X)$ be a three dimensional terminal singularity. Then $4 / \operatorname{index}(X) \geq \operatorname{discrep}(X)$.
Proof. Kawamata shows that in fact $\operatorname{discrep}(X)=1 / \operatorname{index}(X)$. However we need only this weaker version.

The claim is clear if index $(X) \leq 4$. If $\operatorname{index}(X) \geq 5$ then $X$ is of the form

$$
\left(x y+f\left(z, w^{r}\right)=0\right) / \mathbb{Z}_{r}(a,-a, 0,1) \subset \mathbb{C}^{4} / \mathbb{Z}_{r}(a,-a, 0,1)
$$

## J. KOLLÁR

Let $k=$ ord $f(s, t)$ and consider the weighted blow up $W^{\prime} \rightarrow \mathbb{C}^{4} / \mathbb{Z}_{r}(a,-a, 0,1)$ given by weights

$$
w t(x, y, z, w)=(a+i r, k r-i r-a, r, 1)
$$

Let $X^{\prime} \subset W^{\prime}$ be the birational transform of $X$. Explicit computation yields that the unique exceptional divisor has discrepancy $1 / r$.
6.9.8 Definition. (6.9.8.1) A morphism $f: Y \rightarrow X$ is called crepant if $K_{Y}=$ $f^{*} K_{X}$.
(6.9.8.2) A $\log$ morphism $f:\left(Y, D_{Y}\right) \rightarrow\left(X, D_{X}\right)$ is called log crepant if $K_{Y}+D_{Y}=f^{*}\left(K_{X}+D_{X}\right)$.
(6.9.8.3) Let $(X, B)$ be a klt threefold. By (6.9.4) there is a terminal threefold $(Y, D)$ with $\mathbb{Q}$-factorial singularities and a projective morphism $f: Y \rightarrow$ $X$ such that $f_{*} D=B$ and $K_{Y}+D \equiv f^{*}\left(K_{X}+B\right)$. Set $r(X, B)=r(Y, D)$. By construction discrep $(Y, D)$ is the minimum of the positive discrepancies of exceptional divisors over $(X, B)$. Thus $r(X, B)$ is well defined.

A special case of (6.10) was proved in [Kawamata88], the general form is in [Kollár89]. (6.11) is a strengthening of [Kawamata91c] using the method of [Kollár89].
6.10 Theorem. (Crepant Descent of Flops) Let $X$ be a threefold with canonical singularities. Then
(6.10.1) There is a small projective morphism $f: \bar{X} \rightarrow X$ such that $\bar{X}$ is $\mathbb{Q}$-factorial.
(6.10.2) If $e(X)>0$ and $X$ is $\mathbb{Q}$-factorial then there is a morphism $q: X^{\prime} \rightarrow$ $X$ such that $\rho\left(X^{\prime} / X\right)=1$ and $K_{X^{\prime}} \equiv q^{*} K_{X}$. In particular, $e\left(X^{\prime}\right)=e(X)-1$.
(6.10.3) If $X$ is $\mathbb{Q}$-factorial then $H$-flops exist for any effective divisor $H$.
(6.10.4) If $X$ is $\mathbb{Q}$-factorial then $H$-flops terminate for any effective divisor $H$.
(6.10.5) Let $D$ be a $\mathbb{Q}$-Cartier Weil divisor on $X$. Then $m D$ is Cartier for some

$$
1 \leq m \leq \operatorname{index}(X)^{2^{e(X)}} 3^{2 e(X)}-1
$$

6.11 Theorem. (Crepant Descent of Flips) Let $(X, B)$ be a threefold with klt singularities. Then
(6.11.1) There is a small projective morphism $f:(\bar{X}, \bar{B}) \rightarrow(X, B)$ such that $\bar{X}$ is $\mathbb{Q}$-factorial.
(6.11.2) If $e(X, B)>0$ and $X$ is $\mathbb{Q}$-factorial then there is a morphism $q:\left(X^{\prime}, B^{\prime}\right) \rightarrow(X, B)$ such that $\left(X^{\prime}, B^{\prime}\right)$ is $\mathbb{Q}$-factorial and klt, $\rho\left(X^{\prime} / X\right)=1$ and $K_{X^{\prime}}+B^{\prime} \equiv q^{*}\left(K_{X}+B\right)$. In particular, $e\left(X^{\prime}, B^{\prime}\right)=e(X, B)-1$.
(6.11.3.1) If $X$ is $\mathbb{Q}$-factorial then $H$-flops exist for any effective divisor $H$.
(6.11.3.2) If $X$ is $\mathbb{Q}$-factorial then $\log$ flips exist.
(6.11.4.1) If $X$ is $\mathbb{Q}$-factorial then $H$-flops terminate for any effective divisor $H$.
(6.11.4.2) If $X$ is $\mathbb{Q}$-factorial then $\log$ flips terminate.
(6.11.5) Let $E$ be a $\mathbb{Q}$-Cartier Weil divisor on $X$. Then $m E$ is Cartier for some

$$
1 \leq m \leq r(X, B)^{2} 2^{e(X, B)}\left(\frac{3}{\operatorname{logdiscrep}(X, B)}\right)^{2^{e(X, B)}-1}
$$

6.12 Remark. The proof of these two theorems are almost identical. However, the given formulation hides an essential difference. (6.10) can be formulated in a much stronger form by observing that once we choose a crepant $\mathbb{Q}$-factorial terminalization $f: Y \rightarrow X$ then in the course of the proof we use only properties of threefolds which can be obtained from $Y$ by a sequence of flops. This follows from the fact that $e(X)$ is not changed under flops. In the course of the proof of (6.11) we may encounter a situation when $e(X, B)$ drops under a flip and we need a new terminalization $\left(Y^{\prime}, D^{\prime}\right) \rightarrow\left(X^{+}, B^{+}\right)$to continue. $Y^{\prime}$ is not obtainable from $Y$ by a sequence of flops and flips.
6.13 Proof of (6.10-11). Proof by induction on $e(X, B)$. Let $f: Y \rightarrow X$ be as in (6.7.4) or (6.9.4). $\left(j_{k}\right)$ stands for (6.10.j) or (6.11.j) with the additional assumption that $e(X, B)=k$.

Assume that $e(X, B)=0$. Then $f: Y \rightarrow X$ is small. Thus $1_{0}$ holds and if $X$ is $\mathbb{Q}$-factorial then $f$ is an isomorphism. Thus $2_{0}-5_{0}$ hold by $(6.7,6.9)$.

We assume that $j_{k}$ holds for every $j$ and every $k<e=e(X, B)$, and prove $j_{e}$.

Let $p:(Y, D) \rightarrow(X, B)$ be as in (6.7.4,6.9.4). Set $\left(Y_{0}, D_{0}\right)=(Y, D)$ and $p_{0}=p$. Let $E_{0} \subset Y_{0}$ be a $p_{0}$-exceptional divisor. Then $K_{Y_{0}}+D_{0}+\epsilon E_{0}$ is not $p_{0}$-nef for any $\epsilon>0$. We apply the ( $K_{Y_{0}}+D_{0}+\epsilon E_{0}$ )-MMP on $Y_{0} / X$. After some flops (whose existence and termination is guaranteed by $3_{0}$ and $4_{0}$ ) we get a divisorial contraction and obtain $Y_{1} \rightarrow X$. Let $E_{1} \subset Y_{1}$ be an exceptional divisor. We apply the $\left(K_{Y_{1}}+D_{1}+\epsilon E_{1}\right)$-MMP on $Y_{1} / X$ to obtain $Y_{2} \rightarrow X$, and so on. If we proceed until we do not have any more exceptional divisors left then we obtain a small morphism $Y_{e} \rightarrow X$ and $Y_{e}$ is $\mathbb{Q}$-factorial. This gives $1_{e}$. If we stop at $h: Y_{e-1} \rightarrow X$ then we obtain $2_{e}$. We need to check that $\rho\left(Y_{e-1} / X\right)=1$ (if $X$ is $\mathbb{Q}$-factorial). Let $S \subset Y_{e-1}$ be any divisor. Then $h(S)$ is $\mathbb{Q}$-Cartier. Hence $S \equiv h^{*}(h(S))+c E_{e-1}$ for some constant $c$. Thus [ $E_{e-1}$ ] generates $N_{1}\left(Y_{e-1} / X\right)$.

In order to prove $5_{e}$, first note that by $1_{e}$, it is sufficient to consider the $\mathbb{Q}$-factorial case. If $X$ is $\mathbb{Q}$-factorial, let $q: X^{\prime} \rightarrow X$ be given by $2_{e}$. Let
$E \subset X^{\prime}$ be the exceptional divisor. Let $(1-\alpha)$ be the coefficient of $E$ in $B^{\prime}$. (Thus $\alpha \geq \operatorname{logdiscrep}(X, B)$.) Let $p: E^{\prime} \rightarrow E$ be the normalization. Then by (16.5)

$$
\begin{aligned}
K_{E^{\prime}} & \equiv p^{*}\left(K_{X^{\prime}}+E\right)-\operatorname{Diff}(0) \\
& \equiv p^{*}\left(K_{X^{\prime}}+B^{\prime}\right)+p^{*}(\alpha E)-p^{*}\left(B^{\prime}-(1-\alpha) E\right)-\operatorname{Diff}(0) \\
& \equiv p^{*}(\alpha E)-(\text { effective } \mathbb{Q} \text {-divisor }) .
\end{aligned}
$$

Pick a general $x \in q(E)$ and let $x \in U \subset X$ be an affine neighborhood. Let $H \subset U$ be very ample and let $H^{\prime} \subset q^{-1}(U)$ be $q$-very ample. Then intersecting $\operatorname{dim} q(E)$ general members of $|H|$ containing $x$ and $\operatorname{dim} E-\operatorname{dim} q(E)-1$ general members of $\left|H^{\prime}\right|$ we obtain a surface $B \subset X^{\prime}$ such that $A=B \cap E$ is a curve contracted by $q$. Thus $A$ has negative selfintersection in $B$. Hence

$$
K_{E^{\prime}} \cdot p^{-1} A \leq \alpha E \cdot A=\alpha A \cdot{ }_{B} A<0 .
$$

In our case $\operatorname{dim} E^{\prime}=2$ and from surface classification we know that the minimal resolution of $E^{\prime}$ is a ruled surface. Thus $E^{\prime}$ is covered by rational curves $C_{\lambda}^{\prime}$ such that $0>C_{\lambda}^{\prime} \cdot K_{E^{\prime}} \geq-3$. (In higher dimensions one can use [Miyaoka-Mori86].)

Thus there are rational curves $C_{\lambda}=p\left(C_{\lambda}^{\prime}\right) \subset X^{\prime}$ such that $q\left(C_{\lambda}\right)$ is a point and $0>C_{\lambda} \cdot E \geq-3 \log \operatorname{discrep}(X, B)^{-1}$. Let $D^{\prime}$ be the birational transform of $D$ on $Y$. By $5_{e-1}$ we can find $m_{1}$ and $m_{2}$ such that $m_{1} E$ and $m_{2} D^{\prime}$ are Cartier. Thus

$$
\left(m_{1} E \cdot C_{\lambda}\right) m_{2} D^{\prime}-\left(m_{2} D^{\prime} \cdot C_{\lambda}\right) m_{1} E
$$

is Cartier and is numerically $q$-trivial. Therefore by the base point free theorem [KMM87,3.1.2] it descends to a Cartier divisor on $X$. Thus ( $m_{1} E$. $\left.C_{\lambda}\right) m_{2} D$ is Cartier. $0<-\left(m_{1} E \cdot C_{\lambda}\right) m_{2} \leq 3 \operatorname{logdiscrep}(X, B)^{-1} m_{1} m_{2}$, which proves $5_{e}$.

The proof of $3_{e}$ and $4_{e}$ relies on the Backtracking Method.
Let $f: X \rightarrow Z$ be a small contraction which we want to flop or flip. The flop or flip of $f$ can be obtained as a sequence of flops or flips where the relative Picard number is one. Thus we only need to deal with the case $\rho(X / Z)=1$.

Set $\left(X^{0}, B^{0}\right)=(X, \eta H)$ for some $0<\eta \ll 1$ in case (6.10) and $\left(X^{0}, B^{0}\right)=$ $(X, B)$ in case (6.11). $2_{e}$ gives $q_{1}^{0}:\left(Y_{1}^{0}, B_{1}^{0}\right) \rightarrow\left(X^{0}, B^{0}\right)$ such that $K+B_{1}^{0} \equiv$ $\left(q_{1}^{0}\right)^{*}\left(K+B^{0}\right)$. Let $D_{1}^{0}=K+B_{1}^{0} . K+B_{1}^{0}$ is klt. Hence by (6.5.2) and [KMM87,3-2-1] the contractions $r_{i}$ exist and the existence of the opposites follows from $3_{e-1}$.

The sequence of flips terminates by $4_{e-1}$. Thus eventually we get a divisorial contraction $r_{m_{0}}^{0}: Y_{m_{0}}^{0} \rightarrow X_{m_{0}}^{0}$. By (6.5.5) $X_{m_{0}}^{0}=X^{1}$ is the flop (resp. flip) of $f$.

In order to see $4_{e}$ consider a sequence of flops (resp. flips)

$$
\begin{equation*}
X^{0} \xrightarrow{1} \rightarrow X^{1} \rightarrow \cdots . \tag{6.13.1}
\end{equation*}
$$

Our method of flipping starts with a $Y_{1}^{0} \rightarrow X^{0}$ and produces a sequence of flips

$$
Y_{1}^{0} \rightarrow Y_{2}^{0} \xrightarrow{\longrightarrow} \cdots \not Y_{m_{0}}^{0},
$$

ending finally with a contraction $r_{m_{0}}^{0}: Y_{m_{0}}^{0} \rightarrow X^{1}$. We can take

$$
r_{m_{0}}^{0}=q_{1}^{1}: Y_{m_{0}}^{0}=Y_{1}^{1} \rightarrow X^{1}
$$

as the starting point of the sequence of flips constructing $X^{1} \rightarrow X^{2}$. In this way the sequence of flips (6.13.1) gives another sequence

$$
\begin{equation*}
Y_{1}^{0} \rightarrow \cdots \rightarrow Y_{m_{0}}^{0}=Y_{1}^{1} \rightarrow \cdots \rightarrow Y_{m_{1}}^{1}=Y_{1}^{2} \rightarrow \cdots . \tag{6.13.2}
\end{equation*}
$$

(6.13.2) is a sequence of flips but when we go from $Y_{m_{i}}^{i}$ to $Y_{1}^{i+1}$ the relevant divisor may change. Indeed, $D_{m_{i}}^{i}$ is seminegative on $Y_{m_{i}}^{i} \rightarrow X^{i+1}$ while $D_{1}^{i+1}$ is numerically trivial on $Y_{m_{i}}^{i}=Y_{1}^{i+1} \rightarrow X^{i+1}$. Therefore

$$
\begin{equation*}
B_{1}^{i+1}=B_{m_{i}}^{i}-c_{i} E_{i} \quad \text { for some } c_{i} \geq 0, \tag{6.13.3}
\end{equation*}
$$

where $E_{i}$ is the exceptional divisor of $q_{1}^{i}$. Let $c\left(E_{i}\right)$ be the coefficient of $E_{i}$ in $B_{1}^{i}$. Then by (6.13.3)

$$
\begin{equation*}
c\left(E_{j}\right)=c\left(E_{0}\right)-\sum_{i=0}^{j-1} c_{i} . \tag{6.13.4}
\end{equation*}
$$

Choose $N$ such that that $N B^{0}$ is a Weil divisor on $X^{0}$. Then so are the birational transforms $N B^{i}$ on $X^{i}$ for every $i$. By $5_{e}$ there is a universal $M(e)$ such that $M(e)\left(N K+N B^{i}\right)$ is Cartier for every $i$. Thus

$$
M(e) N\left(K+B_{1}^{i}\right)=\left(q_{1}^{i}\right)^{*} M(e)\left(N K+N B^{i}\right)
$$

is a Cartier, hence a Weil divisor. Thus $M(e) N B_{m_{i}}^{i}$ is also a Weil divisor. Comparing this with (6.13.3) we conclude that $M(e) N c_{i}$ is an integer.

If $c_{i}=0$ for $i \geq N$ then the sequence of flips starting with $X^{N}$ lifts to an infinite sequence of flips starting with $Y_{1}^{N}$, which is impossible. Otherwise $c_{i} \geq 1 /(M(e) N)$ for infinitely many values of $i$, hence $c\left(E_{j}\right)<0$ for some $j$.

In case (6.10) this is impossible since $c\left(E_{j}\right)$ is the coefficient of $E_{j}$ in the effective divisor $B_{1}^{j}=\eta\left(q_{1}^{j}\right)^{*} H_{j}$.

In case (6.11) this means that the discrepancy of $E_{j}$ in $Y_{1}^{j} \rightarrow X^{j}$ is greater than 0 . Thus $e\left(X^{j}, B^{j}\right)<e(X, B)$ and again we are done by induction.

One of the main applications of (6.10) is the following generalization of (4.7):
6.14 Theorem. [Kawamata88] Let $X$ be a threefold with log terminal singularities. Let $D$ be a Weil divisor on $X$. Then

$$
\sum_{m=0}^{\infty} \mathcal{O}_{X}(m D)
$$

is a finitely generated $\mathcal{O}_{X}$-algebra.
Proof. By taking the index one cover as in (4.7) it is sufficient to consider the case when $K_{X}$ is Cartier and hence $X$ has canonical singularities.

Let $p: \bar{X} \rightarrow X$ be given by (6.10.1). Let $\bar{D}$ be the birational transform of $D$ on $\bar{X}$.

We apply the $(K+\epsilon \bar{D})$-MMP on $\bar{X} / X$ for some $0<\epsilon \ll 1$. The existence and termination of flops is given by (6.10.3-4). Finally we obtain $p^{+}: \bar{X}^{+} \rightarrow$ $X$ such that $\bar{D}^{+}$is $p^{+}$-nef. By base point freeness [KMM87,3-1-2] there is a morphism

$$
p^{+}: \bar{X}^{+} \xrightarrow{s} Y \xrightarrow{q} X
$$

such that $s\left(\bar{D}^{+}\right)$is $\mathbb{Q}$-Cartier and $q$-ample. Thus by (4.2) the exsitence of $q: Y \rightarrow X$ proves finite generation for $D$.

The following strengthening of (6.11) is needed in Chapter 8.
6.15 Proposition. Let $(X, B)$ be a log terminal $\mathbb{Q}$-factorial threefold. Then log flips exist and any sequence of them is finite.

Proof. Let $g:(X, B) \rightarrow Z$ be a small contraction such that $-(K+B)$ is $g$ ample. Then $-(K+(1-\epsilon) B)$ is $g$-ample and $(X,(1-\epsilon) B)$ is klt for $0<\epsilon \ll 1$. Thus the flip exists by (6.11) (cf. (2.32.1)).

The proof of termination works in the more general case when $(X, B)$ is lc and is klt outside $\llcorner B\lrcorner$. Let $\left(X_{0}, B_{0}\right)=(X, B)$ and consider a sequence of log flips

$$
\left(X_{i}, B_{i}\right) \xrightarrow{g_{i}} Z_{i} \stackrel{g_{i}^{+}}{\leftarrow}\left(X_{i}^{+}, B_{i}^{+}\right)=\left(X_{i+1}, B_{i+1}\right) .
$$

Let $C_{i} \subset X_{i}$ be the flipping curve. By (7.1) $C_{i} \cap\left\llcorner B_{i}\right\lrcorner=\emptyset$ for all but finitely many values of $i$. Thus by shifting the index $i$ we may assume that $C_{i} \cap\left\llcorner B_{i}\right\lrcorner=\emptyset$ for every $i$. We may as well replace $X_{i}$ by $X_{i} \backslash\left\llcorner B_{i}\right\lrcorner$; hence we may assume that $\left\llcorner B_{i}\right\lrcorner=\emptyset$, which implies (cf. (2.13)) that ( $X_{i}, B_{i}$ ) is klt for every $i$. Termination follows from (6.11).

Finally we prove a result about partial resolutions of singularities of threefolds.
6.16 Theorem. Let $(Z, B)$ be a threefold $Z$ and a $\mathbb{Q}$-divisor $B=\sum b_{i} B_{i}$ where the $B_{i}$ have no common components and $0 \leq b_{i} \leq 1$.

Let $0 \leq d \leq 1$ be arbitrary. Then there is a proper birational morphism

$$
p: Z_{d}^{l t} \rightarrow Z
$$

with the following properties:
(6.16.1.1) $\left(Z_{d}^{l t}, p_{*}^{-1}(B)+d E\right)$ is $\mathbb{Q}$-factorial and $\log$ terminal where $E$ is the reduced exceptional divisor of $p$;
(6.16.1.2) $\operatorname{logdiscrep}\left(Z_{d}^{l t}, p_{*}^{-1}(B)+d E\right) \geq 1-d$ and $>1-d$ if $\llcorner B\lrcorner=\emptyset ;$
(6.16.1.3) $K+p_{*}^{-1}(B)+d E$ is $p$-nef.

Furthermore, there is a factorization

$$
p: Z_{d}^{l t} \rightarrow Z_{d}^{l c} \xrightarrow{q} Z
$$

such that
(6.16.2.1) $\left(Z_{d}^{l c}, q_{*}^{-1}(B)+d F\right)$ is $\log$ canonical, where $F$ is the reduced exceptional divisor of $q$;
(6.16.2.2) logdiscrep $\left(Z_{d}^{l c}, q_{*}^{-1}(B)+d F\right) \geq 1-d ;$
(6.16.2.3) $K+q_{*}^{-1}(B)+d F$ is $q$-ample.
(6.16.3) For fixed $d, q: Z_{d}^{l c} \rightarrow Z$ is unique.

Proof. Let $f: X \rightarrow Z$ be a $\log$ resolution such that $f_{*}^{-1}(B)$ is smooth. Let $D$ be the reduced exceptional divisor. Apply the $\left(f_{*}^{-1}(B)+d D\right)$-MMP over $Z$. By (4.12.1)

$$
\operatorname{logdiscrep}\left(X, f_{*}^{-1}(B)+d D\right) \geq 1-d \quad \text { resp. }(>1-d \text { if }\llcorner B\lrcorner=\emptyset)
$$

By (6.15) the program terminates with $p: Z_{d}^{l t} \rightarrow Z$.
In order to obtain $Z_{d}^{l c}$ we need to apply base point freeness [KMM87,3-1-2] to $K+g_{*}^{-1}(B)+d E$. We are done if $\llcorner B\lrcorner=\emptyset$ and $d<1$. In the general case the required base point freeness is proved in Chapter 8.

Uniqueness follows from (2.22).

# 7. TERMINATION OF 3-FOLD LOG FLIPS NEAR THE REDUCED BOUNDARY 

János Kollár and Kenji Matsuki

In this chapter we prove termination of a sequence of 3-fold log flips near the reduced part of the boundary. The role of this result is two fold. First, it completes the results about existence and termination of log flips proved in Chapters 4-6. Second, it is an essential part of the second proof of log flips. (7.1) is slightly more general than the original theorem in [Shokurov91,4.1]. Kawamata kindly informed us that Shokurov himself announced the theorem in this generalized form in a letter.

As in Chapter 4, the proof consists of two major steps:
(I) By considering a finite set of special discrete valuations associated to the flipped curves, we show that after finitely many flips no flipped curve is contained in (the birational transform of) the reduced part of the boundary.
(II) Then, using the finiteness of the Picard number of the reduced part of the boundary, we show that after finitely many flips no flipping curve is contained in it.
7.1 Theorem. Let $X$ be a normal 3-fold and $B$ an effective $\mathbb{Q}$-divisor such that $(X, B)$ is log canonical. Assume that $X$ is $\mathbb{Q}$-factorial. Consider a sequence of log flips starting from $(X, B)=\left(X_{0}, B_{0}\right)$ :

where $\phi_{i}: X_{i} \rightarrow Z_{i}$ is a contraction of an extremal ray $R_{i}$ with $\left(K_{X_{i}}+B_{i}\right)$. $R_{i}<0$, and $\phi_{i}^{+}: X_{i}^{+}\left(=X_{i+1}\right) \rightarrow Z_{i}$ is the log flip. Then after finitely many flips, all the flipping curves (and thus all the flipped curves) are disjoint from $\left\llcorner B_{i}\right\lrcorner$.

Proof. The proof is given in several steps.
7.2 Definition. The notions of semi log category are explained in Chapter 16. Let $(X, B)$ be semi log canonical (16.9). We say that a (not necessarily closed) point $p \in X$ is a maximally log canonical point of $(X, B)$ if there is a divisor $E$ dominating $p$ such that $a(E, X, B)=-1$.
For example, the maximally log canonical points of an slc surface $(S, D)$ are the following: double curves of $S$; irreducible components of $\llcorner D\lrcorner$; closed points where $(S, D)$ is not slt; and singular points of $\llcorner D$.
7.2.1 Proposition. If $X$ is a variety (any dimension) then the number of maximally log canonical points of $(X, B)$ is finite.

Proof. Let $f: Y \rightarrow X$ be a $\log$ resolution of $(X, B)$. (4.12.1) implies that the maximally $\log$ canonical points are the (general points of) $f\left(E_{i_{1}} \cap \cdots \cap E_{i_{k}}\right)$ where $E_{i_{j}} \subset Y$ are divisors with $a\left(E_{i_{j}}, X, B\right)=-1$.
7.2.2 Notation. Let $S_{i}=\left\llcorner B_{i}\right\lrcorner$ and $D_{i}=\operatorname{Diff}_{S_{i}}\left(B_{i}-\left\llcorner B_{i}\right\lrcorner\right)$. Note that by (16.9) $\left(S_{i}, D_{i}\right)$ is semi $\log$ canonical. Furthermore let $\pi_{i}: S_{i}^{\nu} \rightarrow S_{i}$ be the normalization of $S_{i}$ and let $\pi_{i}^{*}\left(K+D_{i}\right)=K+D_{i}^{\nu}$. Thus $D_{i}^{\nu}=\pi_{i}^{*}\left(D_{i}\right)+\Theta_{i}$ where $\Theta_{i} \subset S_{i}^{\nu}$ is the divisor of double curves. Set $E_{i}=\left\llcorner D_{i}^{\nu}\right\lrcorner$.
7.3 First Reduction Step. After finitely many flips, no flipping curve contains a maximally log canonical point of $X$ or of $\left(S_{i}, D_{i}\right)$.

Proof. If a maximally $\log$ canonical point of $X$ is contained in a flipping curve then after a flip the number of maximally $\log$ canonical points decreases by (2.28). Essentially by (16.9), a maximally $\log$ canonical point of $\left(S_{i}, D_{i}\right)$ is also a maximally $\log$ canonical point of $X$.
7.4 Second Reduction Step. After finitely many flips no flipping curve intersects $\pi_{i}\left(E_{i}\right)$.

Proof. This is achieved by analyzing the sequence of pairs ( $S_{i}^{\nu}, D_{i}^{\nu}$ ). Let $\psi_{i}: S_{i}^{\nu} \longrightarrow S_{i+1}^{\nu}$ be the induced map. By (7.3) we may assume that no flipping curve contains a maximally $\log$ canonical point of $\left(S_{i}, D_{i}\right)$. In particular, $E_{i}$ is smooth at the indeterminacies of $\psi_{i}$, thus it induces an isomorphism $\psi_{i}: E_{i} \cong E_{i+1}$. Set $E=E_{1}$ and let $\sigma_{i}: E \cong E_{i}$ be the induced isomorphism.
7.4.1 Claim. Under the above isomorphism

$$
\operatorname{Diff}_{E_{i+1}}\left(D_{i+1}^{\nu}-E_{i+1}\right)=\psi_{i}\left(\operatorname{Diff}_{E_{i}}\left(D_{i}^{\nu}-E_{i}\right)-H_{i}\right)
$$

where $H_{i}$ is an effective $\mathbb{Q}$-divisor and

$$
\operatorname{Supp} H_{i}=\pi_{i}^{-1}\left(\pi_{i}\left(E_{i}\right) \cap \text { flipping curve }\right)
$$

Proof. Let $T_{i}$ be the normalization of $\phi_{i}\left(S_{i}^{\nu}\right)$. By construction we have morphisms

$$
\begin{equation*}
S_{i}^{\nu} \xrightarrow{\rho_{i}} T_{i} \stackrel{\rho_{i}^{+}}{\longleftrightarrow}\left(S_{i}^{\nu}\right)^{+}=S_{i+1}^{\nu}, \tag{7.4.1.1}
\end{equation*}
$$

$-\left(K_{S_{i}^{\nu}}+D_{i}^{\nu}\right)$ is $\rho_{i}$-ample and $K_{S_{i+1}^{\nu}}+D_{i+1}^{\nu}$ is $\rho_{i}^{+}$-ample. If $F$ is any divisor then by (2.28)

$$
\begin{equation*}
a\left(F, S_{i}^{\nu}, D_{i}^{\nu}\right) \leq a\left(F, S_{i+1}^{\nu}, D_{i+1}^{\nu}\right), \tag{7.4.1.2}
\end{equation*}
$$

and strict inequality holds if $\psi_{i}$ is not an isomorphism at $\operatorname{Center}_{S_{i}^{\nu}}(F)$.
The coefficient of the different can be related to discrepancies as follows.
Let $W_{i}$ be a common good resolution of ( $S_{i}^{\nu}, D_{i}^{\nu}$ ) and ( $S_{i+1}^{\nu}, D_{i+1}^{\nu}$ ). Let $p \in E_{i}$ be a point and let $p^{\prime} \in E_{i}^{\prime} \subset W_{i}$ be the corresponding point of the birational transform. Since $W$ is a good resolution, there is at most one exceptional curve $F \subset W_{i}$ intersecting $E_{i}^{\prime}$ at $p^{\prime}$ (by further blowing up we may assume that $F$ is exceptional over both $S_{i}^{\nu}$ and $S_{i+1}^{\nu}$ ). By (17.2.3) the coefficient of $p$ in $\operatorname{Diff}_{E_{i}}\left(D_{i}^{\nu}-E_{i}\right)$ is exactly $-a\left(F, S_{i}^{\nu}, D_{i}^{\nu}\right)$. Thus (7.4.1.2) implies (7.4.1).
7.4.2 Corollary. Notation as above. If a flipping curve intersects $\pi_{i}\left(E_{i}\right)$ then it intersects it at a point of

$$
\pi_{i}\left(\operatorname{Supp}\left(\operatorname{Diff}_{E_{i}}\left(D_{i}^{\nu}-E_{i}\right)\right)\right)
$$

In order to use (7.4.1) we need two further results:
7.4.3 Lemma. [Shokurov91, 4.2] Let $0<b_{i} \leq 1, n_{j}, l \in \mathbb{N}^{+}$and $k_{i j}, l_{j} \in \mathbb{N}$. Assume that

$$
\begin{align*}
d_{j} & =\frac{n_{j}-1}{n_{j}}+\sum_{i} \frac{k_{i j} b_{i}}{n_{j}} \leq 1, \quad \text { and }  \tag{7.4.3.1}\\
p & =\frac{l-1}{l}+\sum_{j} \frac{l_{j} d_{j}}{l}<1 . \tag{7.4.3.2}
\end{align*}
$$

Then there are $m, m_{i} \in \mathbb{N}$ such that

$$
p=\frac{m-1}{m}+\sum_{i} \frac{m_{i} b_{i}}{m} .
$$

Proof. If $n_{j}=1$ for all $j$ with $l_{j} \geq 1$, then this is obvious. Otherwise, there exists a unique $j_{0}$ such that $n_{j_{0}} \geq 2$ and $l_{j_{0}} \geq 1$, for if there were 2 or more, then

$$
p \geq \frac{l-1}{l}+\frac{1}{l}\left(\frac{1}{2}+\frac{1}{2}\right)=1 .
$$

Similarly we obtain $l_{j_{0}}=1$. Hence

$$
\begin{aligned}
p & =\frac{l-1}{l}+\frac{1}{l}\left(\frac{n_{j_{0}}-1}{n_{j_{0}}}+\sum_{i} \frac{k_{j_{0} i}}{n_{j_{0}}} b_{i}\right)+\sum_{j \neq j_{0}} \frac{l_{j}}{l}\left(\sum_{i} k_{j i} b_{i}\right) \\
& =\frac{n_{j_{0}} l-1}{n_{j_{0}} l}+\sum_{i} \frac{k_{j_{0} i}+\sum_{j \neq j_{0}} n_{j_{0}} l_{j} k_{j i}}{n_{j_{0}} l} b_{i}
\end{aligned}
$$

7.4.4 Lemma. Fix a sequence of numbers $0<b_{i} \leq 1$ and $c>0$. Then there are only finitely many possible values $m, m_{i} \in \mathbb{N}$ such that

$$
\frac{m-1}{m}+\sum_{i} \frac{m_{i} b_{i}}{m} \leq 1-c
$$

Proof. It is easy to see that $m \leq c^{-1}$ and $m_{i} \leq c^{-1} b_{i}^{-1}$.
7.4.5 Proof of (7.4). Let $B=\sum b_{j} B_{j}$ and let $D_{i}^{\nu}=\sum d_{j}^{i} D_{j}^{i}$. By (16.6.4), we can write $d_{j}^{i}$ in the form (7.4.3.1). Let $p$ be any of the coefficients occurring in $\operatorname{Diff}_{E_{i}}\left(D_{i}^{\nu}-E_{i}\right)$. Then by (16.6.4) $p$ is of the form (7.4.3.2). Thus by (7.4.4) there are only finitely many possible values for $p$. By (7.4.1) $\sigma_{i}^{*} \operatorname{Diff}_{E_{i}}\left(D_{i}^{\nu}-E_{i}\right)$ is a decreasing sequence of effective divisors on $E$ which is strictly decreasing whenever the flipping curve intersects $\pi_{i}\left(E_{i}\right)$. Since there are only finitely many possibilities for the coefficients, the sequence must stabilize.
7.5 Third Reduction Step. After finitely many flips no flipped curve is contained in $S_{i}^{+}$.
Proof. By (7.3.2) we may assume that no flipping curve intersects $\pi_{i}\left(E_{i}\right)$. We introduce another version of difficulty (cf. (4.12.3)):
7.5.1 Definition. Fix a finite set of positive numbers $\mathbf{b}=\left\{b_{j}\right\}$. Let $(S, D)$ be an slc surface. Assume first that $S$ does not contain any maximally log canonical points (i.e. it is sklt). Let

$$
d_{\mathbf{b}}(S, D)=\sum_{m \in \mathbb{N}^{+}, r_{j} \in \mathbb{N}} \#\left\{E \left\lvert\, a(E, S, D)<-\left(1-\frac{1}{m}+\sum \frac{r_{j} b_{j}}{m}\right)\right.\right\} .
$$

In general, if $Z \subset S$ is the set of maximally $\log$ canonical points then let

$$
d_{\mathbf{b}}(S, D) \xlongequal{\text { def }} d_{\mathbf{b}}(S-\bar{Z}, D)
$$

7.5.2 Lemma. Let $(S, D)$ be an slc surface. Then $d_{\mathbf{b}}(S, D)<\infty$.

Proof. We may assume that $S$ has no maximally $\log$ canonical points. Each of the summands in (7.5.1) is finite by (4.12.2). By (7.4.4) we have only finitely many nonzero summands.
7.5.3 Lemma. Let

$$
X_{i} \xrightarrow{\phi_{i}} Z_{i} \stackrel{\phi_{i}^{+}}{\longleftrightarrow} X_{i+1}
$$

be a flip. Assume that the flipping curve does not intersect $\pi_{i}\left(E_{i}\right)$. Let $\mathbf{b}=\left\{b_{j}\right\}$ be the set of coefficients of the irreducible components $B_{i}$. Then

$$
d_{\mathbf{b}}\left(S_{i}, D_{i}\right) \geq d_{\mathbf{b}}\left(S_{i}^{+}, D_{i}^{+}\right)=d_{\mathbf{b}}\left(S_{i+1}, D_{i+1}\right)
$$

Furthermore, the inequality is strict if $S_{i}^{+}$contains a flipped curve.
Proof. Let $T_{i}=\phi_{i}\left(S_{i}\right)$. By construction we have morphisms $S_{i} \rightarrow T_{i} \leftarrow$ $S_{i}^{+}=S_{i+1}$. Furthermore, $-\left(K_{S_{i}}+D_{i}\right)$ is $\left(S_{i} / T_{i}\right)$-ample and $K_{S_{i}^{+}}+D_{i}^{+}$is $\left(S_{i}^{+} / T_{i}\right)$-ample. If $E$ is any divisor then by (2.28) $a\left(E, S_{i}, D_{i}\right) \leq a\left(E, S_{i}^{+}, D_{i}^{+}\right)$ which shows the first claim.

Assume that $\phi_{i}^{+}$is not an isomorphism. Let $C^{+}$be an exceptional curve of $\phi_{i}^{+}$. Then by (2.28) and (16.6.7)

$$
a\left(C^{+}, S_{i}, D_{i}\right)<a\left(C^{+}, S_{i}^{+}, D_{i}^{+}\right)=-\left(1-\frac{1}{m}+\sum \frac{r_{j} b_{j}}{m}\right)
$$

for some $m, r_{j} \in \mathbb{N}$. Thus $d_{\mathbf{b}}\left(S_{i}, D_{i}\right)>d_{\mathbf{b}}\left(S_{i+1}, D_{i+1}\right)$.
Clearly (7.5.2) and (7.5.3) imply (7.5).
7.6 Fourth Reduction Step. Assume that no flipped curve is contained in $S_{i}^{+}=\left\llcorner B_{i}^{+}\right\lrcorner$. Then after finitely many flips no flipping curve is contained in $S_{i}=\left\llcorner B_{i}\right\lrcorner$.

Proof. Using the notation of (7.5.3) we obtain that $T_{i} \cong S_{i}^{+}$and $S_{i} \rightarrow T_{i}$ contracts a curve. Thus the Picard number of $S_{i}$ decreases after a flip. This cannot be repeated infinitely many times.
7.7 Proof of (7.1). By (7.5) and (7.6) after finitely many steps neither a flipping nor a flipped curve can be contained in the reduced part of the boundary. As in (4.13.3) this implies that the flipping curves are disjoint from the reduced part of the boundary. This completes the proof.

## 8. LOG CANONICAL FLIPS

Sean Keel and János Kollár

The aim of this chapter is to prove the existence of $\log$ flips in the log canonical case. In (8.4) we extend this to a general base point freeness result for $\log$ canonical threefolds.
8.1 Theorem. Let $(Y, \Delta)$ be log canonical and let $g: Y \rightarrow Z$ be a small contraction such that $K_{Y}+\Delta$ is $g$-negative. Then the flip of $g$ exists.

Proof. The problem is local on $Z$. Thus we may assume that $Z$ is a neighborhood of a point $0 \in Z$ which we shrink if necessary without further comments. As in (2.34) we may assume that $\llcorner\Delta\lrcorner=\emptyset$. This somewhat simplifies the argument.

Let $Y^{\prime} \rightarrow Y$ be a $\log$ resolution of $Y$. Let $\Delta^{\prime}=\Delta_{Y^{\prime}}($ (cf. (2.7)). Apply the $\log$ MMP to $\left(Y^{\prime}, \Delta^{\prime}\right) \rightarrow Z$. During the program every occurring pair ( $Y_{i}^{\prime}, \Delta_{i}^{\prime}$ ) is $\log$ terminal and $\mathbb{Q}$-factorial. Log flips exist and terminate by (6.15). Thus eventually the program stops with $f:\left(X, \Delta_{X}\right) \rightarrow Z$ such that $K_{X}+\Delta_{X}$ is $f$-nef, $X$ is $\mathbb{Q}$-factorial and $\left(X, \Delta_{X}\right)$ is $\log$ terminal.

In general $f$ is not an isomorphism over $Z-0$. If $L \subset Z-0$ is a curve along which $\left(Z, \Delta_{Z}\right)$ is not $\log$ terminal then $f$ is not an isomorphism over $L$ but gives a $\log$ terminal model. Therefore

$$
\begin{equation*}
m_{0}\left(K_{X}+\Delta_{X} \mid X-f^{-1}(0)\right) \cong f^{*}\left(m_{0}\left(K_{Z}+\Delta_{Z}\right) \mid Z-0\right) \tag{8.1.1}
\end{equation*}
$$

for suitable $m_{0}>0$.
Let $h: V \rightarrow X$ be any resolution and let

$$
K_{V}=h^{*}\left(K_{X}+\Delta_{X}\right)+\sum a_{i} F_{i}
$$

Since $Y$ is lc, $a_{i} \geq-1$ for every $i$. Furthermore, by (2.23.3) $X$ has the following property:

$$
\begin{equation*}
\text { if } f \circ h\left(F_{i}\right)=0 \in Z \text { then } a_{i}>-1 . \tag{8.1.2}
\end{equation*}
$$

S. M. F.

By (2.22.3) we need to show that $\mathcal{O}_{X}\left(n\left(K_{X}+\Delta_{X}\right)\right)$ is generated by global sections for some $n>0$. The usual base point freeness theorem ([KMM87,3-1-2]) does not apply, since ( $X, \Delta_{X}$ ) is not klt.

Let $\Theta=\left\llcorner\Delta_{X}\right\lrcorner$. We want to modify our model $X$ to achieve that $K_{X}+\Delta_{X}-$ $\epsilon \Theta$ is $f$-nef for $1 \gg \epsilon>0$. Let $p \in f(\Theta)$ be a generic point. Then Spec $\mathcal{O}_{p, Z}$ is a $\log$ canonical surface singularity and $f: X \rightarrow Z$ is a log terminal model of Spec $\mathcal{O}_{p, Z}$. From the list of Chapter 3 we see that $\Theta$ is negative semidefinite on general fibers of $\Theta \rightarrow Z$. This implies that a $\left(K_{X}+\Delta_{X}-\epsilon \Theta\right)$-extremal contraction never contracts a component of $\Theta$.

Let $C=f^{-1}(0)$ (with reduced structure). Choose $1 \gg \epsilon>0 . K_{X}+$ $\Delta_{X}-\epsilon \Theta$ is klt and if $B \subset C$ is an irreducible component such that $\left(K_{X}+\right.$ $\left.\Delta_{X}-\epsilon \Theta\right) \cdot B<0$ then $\left(K_{X}+\Delta_{X}\right) \cdot B=0$. If $B \subset C$ and $B$ generates a $\left(K_{X}+\Delta_{X}-\epsilon \Theta\right)$-extremal ray then the flip of $B$ is a $\left(K_{X}+\Delta_{X}\right)$-flop. Therefore condition (8.1.2) still holds after such a flip and any sequence of such flips is finite by (6.11).

Thus (up to renaming) we may assume that $K_{X}+\Delta_{X}$ is lc, $K_{X}+\Delta_{X}-\epsilon \Theta$ is klt and $f$-nef for $1 \gg \epsilon>0$. By [KMM87,3-1-2] there is an $m_{1}>0$ such that $m_{1}\left(K_{X}+\Delta_{X}-\epsilon \Theta\right)$ is $f$-base point free. Thus

$$
m_{1}\left(K_{X}+\Delta_{X}\right)=m_{1}\left(K_{X}+\Delta_{X}-\epsilon \Theta\right)+m_{1} \epsilon \Theta
$$

is base point free outside $\operatorname{Supp} \Theta$. Therefore it remains to prove base point freeness on $\Theta$ itself.

To this end consider the exact sequence

$$
\begin{align*}
0 \rightarrow \mathcal{O}_{X}\left(m_{1}\left(K_{X}+\Delta_{X}\right)-\Theta\right) & \rightarrow \mathcal{O}_{X}\left(m_{1}\left(K_{X}+\Delta_{X}\right)\right) \\
& \rightarrow \mathcal{O}_{\Theta}\left(m_{1}\left(K_{X}+\Delta_{X}\right) \mid \Theta\right) \rightarrow 0 \tag{8.1.3}
\end{align*}
$$

Observe that

$$
m_{1}\left(K_{X}+\Delta_{X}\right)-\Theta \equiv K_{X}+\left(\Delta_{X}-\Theta\right)+\left(m_{1}-1\right)\left(K_{X}+\Delta_{X}\right)
$$

and $K_{X}+\left(\Delta_{X}-\Theta\right)$ is klt by our assumptions. Thus $R^{1} f_{*} \mathcal{O}_{X}\left(m_{1}\left(K_{X}+\right.\right.$ $\left.\left.\Delta_{X}\right)-\Theta\right)=0$ by [KMM87,1-2-6]. Therefore

$$
\begin{equation*}
f_{*} \mathcal{O}_{X}\left(m_{1}\left(K_{X}+\Delta_{X}\right)\right) \rightarrow f_{*} \mathcal{O}_{\Theta}\left(m_{1}\left(K_{X}+\Delta_{X}\right) \mid \Theta\right) \tag{8.1.4}
\end{equation*}
$$

is surjective. Thus it is sufficient to prove that $\mathcal{O}_{\Theta}\left(m_{1}\left(K_{X}+\Delta_{X}\right) \mid \Theta\right)$ is generated by global sections for suitable $m_{1}>0$.

Let $\Theta_{i}$ be the irreducible components of $\Theta$. By (8.1.2) we see that Sing $\Theta_{i}$ and $\Theta_{i} \cap \Theta_{j}(i \neq j)$ are finite over $Z$. (Otherwise we would get a divisor with discrepancy $\leq-1$ lying over Sing $\Theta_{i}$ or $\Theta_{i} \cap \Theta_{j}$.) By (8.1.1) $m_{0}\left(K_{X}+\Delta_{X}\right) \mid \Theta$ is linearly equivalent to a (not necessarily effective) divisor $D$ supported on the fiber over $0 \in Z$. It is also nef, thus by (8.1.5) $m_{2} m_{0}\left(K_{X}+\Delta_{X}\right) \mid \Theta \sim 0$ for some $m_{2}>0$. By (8.1.4) the constant section of $\mathcal{O}_{\Theta}\left(m_{0} m_{1} m_{2}\left(K_{X}+\Delta_{X}\right) \mid \Theta\right)$ lifts to a section of $\mathcal{O}_{X}\left(m_{0} m_{1} m_{2}\left(K_{X}+\Delta_{X}\right)\right)$ which is nowhere zero along $\Theta$.
8.1.5 Claim. Let $f: \Theta \rightarrow C$ be a proper morphism with connected fibers from a surface to a smooth affine curve. Assume that $\Theta$ is normal at all generic points of $f^{-1}(0)$. Let $D$ be a (not necessarily effective) $\mathbb{Q}$-Cartier divisor supported on $f^{-1}(0)$. Assume that $D$ is nef. Then $m D \sim 0$ for some $m>0$.

Proof. Let $\operatorname{Supp} f^{-1}(0)=\cup C_{i}$ and let $D=\sum d_{i} C_{i}$. By adding a suitable multiple of $f^{-1}(0)$ to $D$ we may assume that

$$
D+\frac{a}{b}\left[f^{-1}(0)\right]=\sum d_{i}^{\prime} C_{i} \quad \text { where } \quad d_{i}^{\prime} \leq 0,
$$

with equality holding for at least one index $i$. Since $D$ is nef, this implies that $d_{i}^{\prime}=0$ for every $i$. Thus $b D \sim-a\left[f^{-1}(0)\right]$.

We are now ready to put the termination of flips in the following final form, due to Matsuki and Mori.
8.2 Theorem. Let $(X, B)$ be a log canonical threefold. Then any sequence of $(K+B)-\log$ flips is finite.
Proof. The case when $X$ is $\mathbb{Q}$-factorial and $\log$ terminal was done in (6.15). Next assume that $X$ is lc and let

\[

\]

be a sequence of flips.
Let $q_{0}:\left(Y_{0}, D_{0}\right) \rightarrow\left(X_{0}, B_{0}\right)$ be a $\mathbb{Q}$-factorial log terminal model as in (8.2.2). $K+D_{0}=q_{0}^{*}\left(K+B_{0}\right)$, thus $K+D_{0}$ is log terminal and not nef on $Y_{0} / Z_{0}$. There is a sequence of divisorial contractions and flips (whose existence and termination is guaranteed by (6.15)) such that at the end we obtain $\left(Y_{1}, D_{1}\right) \rightarrow Z_{0}$ such that $K+D_{1}$ is $\log$ terminal and relatively nef. By definition, $\left(Y_{1}, D_{1}\right) \rightarrow Z_{0}$ is a weak $\log$ canonical model (2.21) of $Y_{0} \rightarrow Z_{0}$. Thus by (2.22.3) there is a morphism $q_{1}: Y_{1} \rightarrow X_{1}$ such that $K+D_{1}=$ $q_{1}^{*}\left(K+B_{1}\right)$. We can continue as before using $Y_{1} \rightarrow X_{1} \rightarrow Z_{1}$. This way a sequence of flips on $X$ lifts to a sequence of flips and divisorial contractions on $Y_{0}$. By (6.15) the sequence terminates on $Y_{0}$, hence the sequence of flips (8.2.1) is also finite.
8.2.2 Lemma. Let $(X, B)$ be an lc threefold. Then there is a projective morphism $q:(Y, D) \rightarrow(X, B)$ such that $(Y, D)$ is $\mathbb{Q}$-factorial, log terminal and $K+D=q^{*}(K+B)$.
Proof. Let $f: X^{\prime} \rightarrow X$ be a $\log$ resolution of $(X, B)$ with reduced exceptional divisor $E$. Apply the $\left(K+f_{*}^{-1}(B)+E\right)$-MMP on $X^{\prime} / X$. By (6.15) all
the steps exist and the program terminates with $q:(Y, D) \rightarrow(X, B)$ such that $K+D$ is $q$-nef. Thus $q: Y \rightarrow X$ is a weak $\log$ canonical model of $(X, B)$. Since $(X, B)$ is lc, it is its own $\log$ canonical model, hence by (2.22.3) $K+D=q^{*}(K+B)$.

The method of (8.1) can be generalized to yield the finite generation of $\log$ canonical rings for threefolds $(X, \Delta)$ of log general type. This is the $\kappa=3$ part of the Abundance Conjecture for lc threefolds. Most of the proof involves analysis of semi log canonical surfaces, therefore it should be read after Chapter 12.

If $(X, \Delta)$ is klt then the result is a special case of base point freeness. [Kawamata91d] settled the lc case under some technical assumptions.
8.3 Definition. Let $X$ be a proper and irreducible variety over a field. Let $L$ be a line bundle on $X$. We say that $L$ is big if there is an $\epsilon>0$ such that

$$
h^{0}\left(X, L^{m}\right)>\epsilon m^{\operatorname{dim} X} \quad \text { for } m \gg 1
$$

(8.3.2) Let $f: X \rightarrow Z$ be a proper morphism; $X$ irreducible. Let $L$ be a line bundle on $X$. We say that $L$ is $f$-big if $L$ is big on the fiber of $f$ over the generic point of $f(X)$.

Thus if $f$ is generically finite then every line bundle is $f$-big.
(8.3.3) Let $(X, B)$ be proper, irreducible and lc. We say that it is of $\log$ general type if $K+B$ is big.
8.4 Theorem. Let $X$ be an irreducible threefold and let $\Delta$ be an effective $\mathbb{Q}$-divisor on $X$. Assume that $K_{X}+\Delta$ is $\log$ canonical. Let $f: X \rightarrow Z$ be a proper morphism and assume that $K_{X}+\Delta$ is $f$-nef and $f$-big. Then $m\left(K_{X}+\Delta\right)$ is $f$-base point free for suitable $m>0$. Thus

$$
\sum_{s=0}^{\infty} f_{*} \mathcal{O}_{X}\left(s\left(K_{X}+\Delta\right)\right) \quad \text { is a finitely generated } \mathcal{O}_{Z} \text {-algebra }
$$

Proof. The proof is similar to the proof of (8.1). As a first step we reduce the problem to abundance on $\llcorner\Delta\lrcorner$. This was already done in [Kawamata91d]. Here we present another proof in the spirit of (8.1) which however uses more.

First we take a log terminal model $h: X^{\prime} \rightarrow X$ to obtain $\left(X^{\prime}, \Delta^{\prime}\right)$. As in (8.1), after some contractions and flips we obtain $f^{\prime \prime}:\left(X^{\prime \prime} ; \Delta^{\prime \prime}\right) \rightarrow Z$ such that
(8.4.1) $\left(X^{\prime \prime}, \Delta^{\prime \prime}\right)$ is lc; and
(8.4.2) $K_{X^{\prime \prime}}+\Delta^{\prime \prime}-\epsilon\left\llcorner\Delta^{\prime \prime}\right\lrcorner$ is klt, $f^{\prime \prime}$-nef and $f^{\prime \prime}$-big for $1 \gg \epsilon>0$.
(Here we can not exclude the possibility that we contract a component of $\left\llcorner\Delta^{\prime}\right\lrcorner$.) From now on we drop the " from our notation. Let $\Theta=\llcorner\Delta\lrcorner$. As in the proof of (8.1) we obtain that
(8.4.3) $m_{1}(K+\Delta)$ is $f$-base point free outside $\operatorname{Supp} \Theta$ for suitable $m_{1}>0$, and
(8.4.4) $f_{*} \mathcal{O}_{X}\left(m_{1}(K+\Delta)\right) \rightarrow f_{*} \mathcal{O}_{\Theta}\left(m_{1}(K+\Delta) \mid \Theta\right)$ is surjective.

Therefore (8.4) is implied by the following (just set $S=\Theta$ and $\Delta=$ $\left.\operatorname{Diff}_{S}(\Delta-\Theta)\right)$ :
8.5 Theorem. Let $S$ be a reduced surface and let $\Delta$ be a $\mathbb{Q}$-Weil divisor on S. Let $f: S \rightarrow Z$ be a proper morphism; $Z$ affine. Assume that $K_{S}+\Delta$ is $\mathbb{Q}$-Cartier, $f$-nef and semi log canonical.

Then the linear system $\left|m\left(K_{S}+\Delta\right)\right|$ is base point free for suitable $m>0$.
Proof. Most of the work is done in Chapter 12 where this is established under the additional assumption that $Z=$ point and $\left(K_{S}+\Delta\right)^{2}=0$. We use the notation and terminology of Chapter 12. As in (12.4) we may assume that $S$ is semismooth.

Let $D \subset S$ be the union of those double curves which are
(i) either contained in at least one irreducible componet of $S$ on which $K_{S}+\Delta$ is $f$-big;
(ii) or proper over $Z$ and contained in a nonproper component of $S$.

Let $p: \bar{S} \rightarrow S$ be the surface obtained by blowing up $D$. The connected components of $\bar{S}$ are as follows:
(8.5.1) One (not necessarily connected) proper, smooth and semi log canonical surface $(X, \Theta)$ such that $K+\Theta$ is $f$-big on every component;
(8.5.2) One (not necessarily connected) proper semi log canonical surface $\left(Y_{1}, \Xi_{1}\right)$ such that $\left(K+\Xi_{1}\right)^{2}=0$.
(8.5.2) One (not necessarily connected) surface $Y_{2}$ whose irreducible components are not proper and the restricion of $K+\Delta$ is not $f$-big on any component. Clearly, $Y_{2}$ satisfies the assumptions of (12.4.7.1), where $B$ is the normalisation of $f\left(Y_{2}\right)$.

Let $Y=Y_{1} \cup Y_{2}$. Let $D_{X}=p^{-1}(D) \mid \cup X_{i}$ and $D_{Y}=p^{-1}(D) \mid Y$. We can decompose $D=D^{1} \cup D^{2} \cup D^{3}$ where $D^{1}$ is the union of those curves whose preimages under $p$ are both in $X, D^{3}$ is the union of those curves whose preimages under $p$ are both in $Y$, and $D^{2}$ are the rest. Together with the morphism $p$ these fit in the following diagram:

\[

\]

where the arrows marked bir are birational. Finally let $\left.C_{X}=\cup_{\llcorner } \Theta_{i}\right\lrcorner$.
By (12.1.1) and (12.4.7.1) abundance holds for $\left(Y_{i}, \Xi_{i}\right)$. For the other components we use the following:
8.6 Lemma. Let $(X, \Theta)$ be an irreducible and $\log$ canonical surface and $f: X \rightarrow Z$ a proper morphism; $Z$ affine. Assume that $K+\Theta$ is $f$-nef and $f$-big. Let $C=\llcorner\Theta\lrcorner$. Let $m>0$ be such that $m(K+\Theta)$ is Cartier and let

$$
s_{i} \in H^{0}\left(C, \mathcal{O}\left(m\left(K_{X}+\Theta\right) \mid C\right)\right)
$$

be sections without common zeros. Let $x \in X$ be an arbitrary point.
Then there is an $r>0$ and a section $s \in H^{0}\left(X, \mathcal{O}\left(r m\left(K_{X}+\Theta\right)\right)\right)$ such that
(8.6.1) $s(x) \neq 0$;
(8.6.2) the image of $s$ under the restriction map

$$
\text { res : } H^{0}\left(X, \mathcal{O}\left(r m\left(K_{X}+\Theta\right)\right)\right) \rightarrow H^{0}\left(C, \mathcal{O}\left(r m\left(K_{X}+\Theta\right) \mid C\right)\right)
$$

is one of the sections $s_{i}^{r}$.
Proof. Let us prove first that $k(K+\Theta)$ is base point free for some $k>0$. As before, we may assume that $K+\Theta-\epsilon C$ is klt and nef for $1 \gg \epsilon>0$. Thus $k(K+\Theta)$ is base point free outside $C$ and we are reduced to establishing base point freeness for $(C,(K+\Theta) \mid C) .(K+\Theta) \mid C=K_{C}+\operatorname{Diff}(\Theta-C)$, hence base point freeness holds by (12.2.11). Thus we obtain base point freeness for $k(K+\Theta)$. This gives a factorisation

$$
f:(X, \Theta) \xrightarrow{h}\left(X^{\prime}, \Theta^{\prime}\right) \xrightarrow{f^{\prime}} Z,
$$

such that $k\left(K+\Theta^{\prime}\right)$ is an $f^{\prime}$-ample Cartier divisor and $k(K+\Theta)=h^{*}(k(K+$ $\left.\Theta^{\prime}\right)$ ).

Assume first that $h(x)=h(c)$ for some $c \in C$. Choose $s_{i}$ such that $s_{i}(c) \neq$ 0 . As in (8.1.4) res is surjective, thus there is $s \in H^{0}\left(X, \mathcal{O}\left(m\left(K_{X}+\Theta\right)\right)\right)$ such that res $(s)=s_{i}$. Since $s$ pulls back from $X^{\prime}$, we conclude that $s(x) \neq 0$.

If $h(x)$ and $h(C)$ are disjoint, choose $r$ large enough so that in the following diagram the horizontal arrows are surjective $(\mathbb{C}(x)$ is the residue field of $x \in$ $X)$ :

Thus any of the $s_{i}^{r k}$ can be lifted to a suitable $s$.
(8.7) Proof of (8.5). By (12.1.1) and (12.4.7.1) $\mathcal{O}\left(m\left(K_{Y}+\Xi\right)\right.$ ) is generated by normalised sections $\sigma_{j}$ for suitable $m>0$. These restrict to normalized sections

$$
\sigma_{j} \mid D_{Y}^{2} \in H^{0}\left(D_{Y}^{2}, \mathcal{O}\left(m p^{*}\left(K_{S}+\Delta\right) \mid D_{Y}^{2}\right)\right)=H^{0}\left(D_{Y}^{2}, \mathcal{O}\left(m\left(K_{Y}+\Xi\right) \mid D_{Y}^{2}\right)\right) .
$$

Thus $\sigma_{j} \mid D_{Y}^{2}$ induces a normalised section

$$
\rho_{j} \in H^{0}\left(D_{X}^{2}, \mathcal{O}\left(m p^{*}\left(K_{S}+\Delta\right) \mid D_{X}^{2}\right)\right) .
$$

On $D_{X}^{1}$ we can choose normalised sections

$$
\tau_{k} \in H^{0}\left(D_{X}^{1}, \mathcal{O}\left(m\left(K_{S}+\Delta\right) \mid D_{X}^{1}\right)\right)
$$

which have no common zeros (if necessary we may replace $m$ by $12 m$ ). By (12.2.11) $\rho_{j}$ and $p^{*} \tau_{k}$ extend to a normalised section

$$
s_{j k} \in H^{0}\left(C_{X}, \mathcal{O}\left(m p^{*}\left(K_{S}+\Delta\right) \mid C_{X}\right)\right),
$$

and we may assume that the $s_{j k}$ have no common zeros (this may require several extensions for each pair ( $j, k)$ but we ignore this in the notation).

Finally by (8.6) we can extend these to sections

$$
s_{j k}^{r} \in H^{0}\left(X, \mathcal{O}\left(m r p^{*}\left(K_{S}+\Delta\right)\right)\right)
$$

such that the $s_{j k}^{r}$ have no common zeros (we may assume that $r$ does not depend on $j, k$ ). By construction $s_{j k}^{r}$ and $\sigma_{j}^{r}$ glue together to sections of $\mathcal{O}\left(m r\left(K_{S}+\Delta\right)\right)$ without common zeros.

# 9. MIYAOKA'S THEOREMS ON THE GENERIC SEMINEGATIVITY OF $T_{X}$ AND ON THE KODAIRA DIMENSION OF MINIMAL REGULAR THREEFOLDS. 

N.I. Shepherd-Barron

### 9.0 Introduction

In this chapter the aim is to prove the following results of [Miyaoka87a,88a], concerning normal complex projective varieties $X$.
9.0.1 Theorem. If $X$ is not uniruled, then $\Omega_{X}^{1}$ is generically semipositive (equivalently, $T_{X}$ is generically seminegative).

In recalling what this means, we use the following notation, which will be fixed throughout this chapter:
$X$ : a normal projective $n$-fold.
$H_{1}, \ldots, H_{n-1}, H$ : ample divisors on $X$.
$\left\{C_{t}\right\}_{t \in S}$ : the complete family of curves of the form $D_{1} \cap \ldots \cap D_{n-1}$, where $D_{i} \in\left|m_{i} H_{i}\right|$ and $m_{i} \gg 0$.
$C$ : a geometric generic member of $\left\{C_{t}\right\}$.
Then $\Omega_{X}^{1}$ is generically semipositive if every torsion free quotient of $\left.\Omega_{X}^{1}\right|_{C}$ has nonnegative degree.

This result follows immediately from the next result.
9.0.2 Theorem. Assume that there is a subsheaf $\mathcal{E} \subset T_{X}$ such that $c_{1}(\mathcal{E})$. $C>0$. Then there is a saturated $\mathcal{F} \subset T_{X}$ such that $c_{1}(\mathcal{F}) \cdot C>0$ and there is a rational curve $M$ through a generic point $x$ of $X$ such that
(i) $M$ is smooth at $x$,
(ii) $T_{M}(x) \hookrightarrow \mathcal{F}(x)$ and
(iii) $(H \cdot M) \leq 2 n(H \cdot C) /\left(c_{1}(\mathcal{F}) \cdot C\right)$.

This result can be extended. Define a variety to be rationally chain connected if two general points on it can be joined by a chain of rational curves.

## N. SHEPHERD-BARRON

9.0.3 Theorem. Assume the hypotheses and notation of (9.0.2). Then the sheaf $\mathcal{F}$ defines a foliation on $X$ whose leaves are compact and are rationally chain connected varieties.

Remark. By abuse of language, we confuse the notions of foliation and integrable distribution, and we say that a foliation with singularities has compact leaves if the closure of each leaf is a projective variety that contains the leaf as a Zariski open subset.

One of the main consequences of (9.0.1) concerns the second Chern class. Recall that $X$ is minimal if it has only terminal singularities and $K_{X}$ is nef.
9.0.4 Theorem. Suppose that $X$ is minimal and that $\rho: Y \rightarrow X$ is a resolution. Then $c_{2}(Y) \cdot \rho^{*} H_{1} \cdots \cdot \rho^{*} H_{n-2} \geq 0$.

Apart from (9.0.1) to prove (9.0.4) we need a consequence of Bogomolov's theorem on unstable vector bundles, which is proved in Chapter 10.
9.0.5 Theorem. Suppose that $\mathcal{E}$ is a reflexive sheaf on $Y$. Put $\mathcal{F}=\left(\rho_{*} \mathcal{E}\right)^{\vee \vee}$, and assume that $\mathcal{F}$ is generically semipositive and that $c_{1}(\mathcal{F})\left(=\rho_{*} c_{1}(\mathcal{E})\right)$ is nef. Then $c_{2}(\mathcal{E}) \cdot \rho^{*} H_{1} \cdots \rho^{*} H_{n-2} \geq 0$.

Then we deduce

### 9.0.6 Theorem. If $X$ is a minimal regular threefold, then $\kappa(X) \geq 0$.

In the course of proving this, we shall assume the corresponding result for irregular threefolds. For this, we refer to [Ueno82] and [Viehweg80].

As we said above, all of these theorems are due to Miyaoka, and indeed our proofs of (9.0.4) and (9.0.6) follow his very closely (except for a slightly slicker use of Donaldson's theorem [Donaldson85] on stable bundles with trivial Chern classes, which was suggested by conversations with Kollár and Kotschick). However, Miyaoka's proof of (9.0.2) uses his theory of deformations of morphisms along foliations [Miyaoka87a], whereas our proof seems to be considerably simpler.

### 9.1 Foliations

In this section we prove
9.0.2(bis) Theorem. Assume that $\mathcal{F} \hookrightarrow T_{X}$ is a subsheaf such that $\mathcal{F}$ is a piece of the Harder-Narasimhan filtration of $T_{X}$ and $\mu_{\min }\left(\left.\mathcal{F}\right|_{C}\right)>0$. (This notation is explained in (9.1.1).)

Then through a geometric generic point $x$ of $X$, there is a rational curve $M$ such that
(i) $M$ is smooth at $x$,
(ii) $T_{M}(x) \subseteq \mathcal{F}(x)$ and
(iii) $(H \cdot M) \leq 2 n(H \cdot C) /\left(c_{1}(\mathcal{F}) \cdot C\right)$.

To prove this we carry out the following steps:
(1) Show that $\mathcal{F}$ is closed under Lie bracket. (2) Reduce $X$ modulo $p$. (3) Show that $\mathcal{F}$ is closed under Lie bracket and taking $p$ th powers, for $p \gg 0$.
(4) Divide $X$ by $\mathcal{F}$, giving a purely inseparable morphism $\rho: X \rightarrow Y=X / \mathcal{F}$.
(5) Note that $\left(\rho^{*} c_{1}(Y) \cdot C\right)>0$ for $p \gg 0$. (6) Find rational curves on $Y$. (7) Pull them back to rational curves on $X$. (8) Lift back to characteristic zero, and check the conclusions of (9.0.2(bis)).

### 9.1.1 Some facts about vector bundles

We collect here, without proofs, some well known definitions and theorems about vector bundles. (See e.g. [Seshadri82, Part 1] for an introduction over curves and [Siu87, Chapter 1] for the higher dimensional properties.)

Let $g$ denote the genus of the curve $C$ above.
9.1.1.1 Suppose that $\mathcal{E}$ is a vector bundle on $C$. Write $\mu(\mathcal{E})=\operatorname{deg}(\mathcal{E}) / r k(\mathcal{E})$. Then there is a unique filtration (the Harder-Narasimhan filtration or H.-N. filtration) of $\mathcal{E}$

$$
0=\mathcal{E}_{0} \subset \mathcal{E}_{1} \subset \ldots \subset \mathcal{E}_{r}=\mathcal{E}
$$

such that if $\mathcal{G}_{i}=\mathcal{E}_{i} / \mathcal{E}_{i-1}$, then $\mathcal{G}_{i}$ is a semistable vector bundle and

$$
\mu\left(\mathcal{G}_{1}\right)>\ldots>\mu\left(\mathcal{G}_{r}\right) .
$$

Write $\mu\left(\mathcal{G}_{1}\right)=\mu_{\max }(\mathcal{E})$ and $\mu\left(\mathcal{G}_{r}\right)=\mu_{\text {min }}(\mathcal{E})$.
9.1.1.2 If $\mathcal{A}$ and $\mathcal{B}$ are vector bundles on $C$ and $\mu_{\min }(\mathcal{A})>\mu_{\max }(\mathcal{B})$, then $\operatorname{Hom}(\mathcal{A}, \mathcal{B})=0$.
9.1.1.3 $\mu(\mathcal{A} \otimes \mathcal{B})=\mu(\mathcal{A})+\mu(\mathcal{B})$ and $\mu\left(\bigwedge^{2} \mathcal{A}\right)=2 \mu(\mathcal{A})$.
9.1.1.4 (char $=0$ ) If $\mathcal{A}$ and $\mathcal{B}$ are semistable, then so are $\Lambda^{2} \mathcal{A}$ and $\mathcal{A} \otimes \mathcal{B}$.
N.B. In characteristic $p>0$, tensor bundles of semistable bundles can be unstable.
9.1.1.5 For any vector bundle $\mathcal{E}$ on $C$, the tensor product $\mathcal{E} \otimes \mathcal{O}(A)$ is generated by its sections if $A \in \operatorname{Pic} C$ with $\operatorname{deg} A>2 g-1-\mu_{\min }(\mathcal{E})$.
9.1.1.6 Given a general point $x$ of $\mathbb{P}(\mathcal{E})$, there is a section $C^{\prime}$ of $\mathbb{P}(\mathcal{E})$ passing through $x$, where $C^{\prime}$ corresponds to a surjection $\mathcal{E} \rightarrow \mathcal{L}$ with $\mathcal{L} \in \operatorname{Pic} C$ and

$$
\operatorname{deg} \mathcal{L}=\operatorname{deg} \mathcal{E}+(\operatorname{rk} \mathcal{E}-1) \cdot\left\ulcorner\left(2 g-\mu_{\min }(\mathcal{E})\right)\right\urcorner .
$$

This follows immediately from (9.1.1.5), by considering the tautological linear system on a suitable $\mathbb{P}(\mathcal{E} \otimes \mathcal{O}(A)$.
9.1.1.7 [Mehta-Ramanathan82] If $\mathcal{E}$ is a torsion-free sheaf on $X$, then there is a unique filtration (the Harder-Narasimhan filtration)

$$
0=\mathcal{E}_{0} \subset \ldots \subset \mathcal{E}_{r}=\mathcal{E}
$$

whose graded pieces are torsion-free and which restricts to the HarderNarasimhan filtration of $\left.\mathcal{E}\right|_{C}$ (cf. [ibid, Introduction and 6.1]).
9.1.1.8 If $X \rightarrow S$ is a family of varieties, where $S$ is a scheme of finite type over a field or excellent Dedekind domain, and $\mathcal{E}$ is a torsion-free sheaf on $X$, flat over $S$, then the points $s \in S$ such that $\mathcal{E}_{s}$ is a stable (resp. semistable) torsion-free sheaf on $X_{s}$ form an open subset of $S$.

### 9.1.2 Foliations in positive characteristic

All we need is what follows. For most of the proofs, we refer to [Ekedahl87], see esp. [ibid,2.4,3.4,4.2].
9.1.2.1 Proposition. Given a normal variety $X$ in char. $p>0$, there is a one-to-one correspondence between
(A) factorizations $X \xrightarrow{\rho} Y \xrightarrow{\sigma} X^{(1)}$ of the geometric Frobenius morphism $F_{X}: X \rightarrow X^{(1)}$, where $\operatorname{deg} \rho=p^{r}$, and
(B) saturated coherent subsheaves $\mathcal{F} \hookrightarrow T_{X}$ such that $\mathrm{rk} \mathcal{F}=r, \mathcal{F}$ is closed under Lie bracket and $\mathcal{F}$ is closed under pth powers.

Such an $\mathcal{F}$ is a 1 -foliation. Write $Y=X / \mathcal{F}$. (Given $\mathcal{F}$, we have $\mathcal{O}_{Y}=\mathcal{O}_{X}^{\mathcal{F}}$, the algebra of functions annihilated by $\mathcal{F}$. Given $\rho$, we get $\mathcal{F}=\operatorname{ker} d \rho$.) If $X$ is smooth, then $Y$ is smooth if and only if $\mathcal{F}$ is a subbundle of $T_{X}$.
9.1.2.2 Proposition. Suppose that $\mathcal{F} \hookrightarrow T_{X}$ is a saturated subsheaf. Then $\mathcal{F}$ is a 1 -foliation if
(i) $\operatorname{Hom}_{\mathcal{O}_{U}}\left(\bigwedge^{2} \mathcal{F}, T_{X} / \mathcal{F}\right)=0$ and
(ii) $\operatorname{Hom}_{\mathcal{O}_{U}}\left(F^{*} \mathcal{F}, T_{X} / \mathcal{F}\right)=0$,
where $F$ is the absolute Frobenius and $U$ is the locus where both $X$ is smooth and $\mathcal{F}$ is a subbundle.
9.1.2.3 Proposition. Suppose that $\mathcal{F} \hookrightarrow T_{X}$ is a 1-foliation. Put $\mathcal{G}=$ $T_{X} / \mathcal{F}$, and let $\rho: X \rightarrow Y=X / \mathcal{F}$ be the quotient by $\mathcal{F}$. Then $\rho^{*} c_{1}(Y)=$ $p \cdot c_{1}(\mathcal{F})+c_{1}(\mathcal{G})$.
Proof. We have a factorization of $F_{X}$ as in (9.1.2.1(A)) and exact sequences

$$
\begin{aligned}
& 0 \rightarrow \mathcal{F} \rightarrow T_{X} \rightarrow \mathcal{G} \rightarrow 0, \\
& 0 \rightarrow \mathcal{A} \rightarrow T_{Y} \rightarrow \mathcal{B} \rightarrow 0,
\end{aligned}
$$

say, where $\mathcal{G} \cong \operatorname{im}\left(T_{X} \rightarrow \rho^{*} T_{Y}\right)=\rho^{*} \mathcal{A}$ and $\mathcal{B} \cong \operatorname{im}\left(T_{Y} \rightarrow \sigma^{*} T_{X^{(1)}}\right)=\sigma^{*} \mathcal{F}^{(1)}$. ( $X$ and $X^{(1)}$ are conjugate $k$-varieties; if $\mathcal{Z}$ is a sheaf on $X$, then $\mathcal{Z}^{(1)}$ is its conjugate on $X^{(1)}$.) So

$$
\rho^{*} c_{1}(Y)=\rho^{*}\left(c_{1}(\mathcal{A})+c_{1}(\mathcal{B})\right)=\rho^{*}\left(c_{1}(\mathcal{A})+\sigma^{*} c_{1}\left(\mathcal{F}^{(1)}\right)\right)=c_{1}(\mathcal{G})+p \cdot c_{1}(\mathcal{F}),
$$

since $c_{1}\left(F_{X}^{*} \mathcal{Z}^{(1)}\right)=p \cdot c_{1}(\mathcal{Z})$ for any sheaf $\mathcal{Z}$ on $X$.

### 9.1.3 Proof of (9.0.2(bis)) (first step)

We suppose given

$$
0 \rightarrow \mathcal{F} \rightarrow T_{X} \rightarrow \mathcal{G} \rightarrow 0
$$

such that $\mathcal{F}$ is a term in the $\mathrm{H} . \mathrm{N}$. filtration of $T_{X}$, and $\mu_{\min }\left(\left.\mathcal{F}\right|_{C}\right)>0$ (so that in particular, $\left.\left(c_{1}(\mathcal{F}) \cdot C\right)>0\right)$.
9.1.3.1 Lemma. (char. $=0) \mathcal{F}$ is closed under Lie bracket.

Proof. Suppose that $\mathcal{A}_{1}, \ldots, \mathcal{A}_{m}$ are the composition factors in the H.-N. filtration of $\left.\mathcal{F}\right|_{C}$, with $\mu\left(\mathcal{A}_{1}\right)>\ldots>\mu\left(\mathcal{A}_{m}\right)$. Then the composition factors in the H.-N. filtration of $\left.\bigwedge^{2} \mathcal{F}\right|_{C}$ are all of the form $\mathcal{A}_{i} \otimes \mathcal{A}_{j}$ or $\Lambda^{2} \mathcal{A}_{i}$, so that $\mu_{\min }\left(\bigwedge^{2} \mathcal{F}_{C}\right)=2 \mu_{\min }\left(\left.\mathcal{F}\right|_{C}\right)$. Hence $\mu_{\min }\left(\bigwedge^{2} \mathcal{F}_{C}\right)>\mu_{\max }\left(\left.\mathcal{G}\right|_{C}\right)$, so that $\operatorname{Hom}\left(\left.\bigwedge^{2} \mathcal{F}\right|_{C},\left.\mathcal{G}\right|_{C}\right)=0$ and then $\operatorname{Hom}\left(\bigwedge^{2} \mathcal{F}, \mathcal{G}\right)=0$.

Now reduce modulo p. (This will hold until the end of (9.1.3).)
9.1.3.2 Lemma. (char $=p>0) \mathcal{F}$ is closed under Lie bracket.

Proof. Immediate from (9.1.3.1), by specialization.
To prove that $\mathcal{F}$ is closed under $p$ th powers, it would be enough to know that $\left.F^{*} \mathcal{F}\right|_{C}$ is semistable. Unfortunately, this need not be true. However, the following result will suffice.
9.1.3.3 Proposition. (char $=p>0$ ) Suppose that $\mathcal{E}$ is a semistable vector bundle of rank $r$ over a curve $C$ of genus $g$, such that $F^{*} \mathcal{E}=\tilde{\mathcal{E}}$, say, is unstable. Then

$$
\mu_{\max }(\tilde{\mathcal{E}})-\mu_{\min }(\tilde{\mathcal{E}}) \leq\left(r^{r}-1\right)(2 g+1) r /(r-1)
$$

([Lange-Stuhler77] have already found such a bound when $r=2$.)
Proof. Recall first that $F^{*} \mathcal{E}=F_{C}^{*} \mathcal{E}^{(1)}$. Suppose that

$$
0 \rightarrow \mathcal{A} \rightarrow \tilde{\mathcal{E}} \rightarrow \mathcal{B} \rightarrow 0
$$

fits into the H .-N. filtration of $\tilde{\mathcal{E}}$. So $\mu_{\min }(\mathcal{A})>\mu_{\max }(\mathcal{B})$. Put $\mathbb{P}_{1}=\mathbb{P}(\mathcal{B}), \tilde{\mathbb{P}}=$ $\mathbb{P}(\tilde{\mathcal{E}}), \mathbb{P}=\mathbb{P}\left(\mathcal{E}^{(1)}\right)$. Then we have a commutative diagram

where the square is Cartesian and $\iota$ is the natural inclusion.
Let $\sigma$ denote the composite $\mathbb{P}_{1} \rightarrow C$.
By (9.1.2.2), there is a line subbundle $\mathcal{H}$ of $T_{\tilde{\mathbb{P}}}$ which is a foliation, such that $\mathbb{P}=\tilde{\mathbb{P}} / \mathcal{H}$. Since the square is Cartesian, we see that $\mathcal{H} \rightarrow \tilde{\pi}^{*} T_{C}$ is an isomorphism.

Now if $\left.\mathcal{H}\right|_{\mathbb{P}_{1}} \hookrightarrow T_{\mathbb{P}_{1}}$, then $\left.\mathcal{H}\right|_{\mathbb{P}_{1}}$ is a nonsingular foliation on $\mathbb{P}_{1}$, and $\mathbb{P}_{1}$ maps $p$-to- 1 to its image in $\mathbb{P}$, giving a subscroll of $\mathbb{P}$ that destabilizes $\mathcal{E}^{(1)}$. Hence $\left.\mathcal{H}\right|_{\mathbb{P}_{1}} \hookrightarrow \mathcal{N}_{\mathbb{P}_{1} / \tilde{\mathbb{P}}}$, so that

$$
\left.\mathcal{H}\right|_{\mathbb{P}_{1}} \hookrightarrow \mathcal{O}_{\mathbb{P}_{1}}(1) \otimes \sigma^{*} \mathcal{A}^{\vee} .
$$

By (9.1.1.6), there is a section $C^{\prime} \hookrightarrow \mathbb{P}_{1}$ in general position such that

$$
\operatorname{deg}\left(\left.\mathcal{O}_{\mathbb{P}_{1}}(1)\right|_{C^{\prime}}\right)=\operatorname{deg} \mathcal{B}+(\operatorname{rk} \mathcal{B}-1) \cdot\left\ulcorner 2 g-\mu_{\min }(\mathcal{B})\right\urcorner .
$$

Restricting $\circledast$ to $C^{\prime}$, we get $T_{C^{\prime}} \hookrightarrow\left(\left.\mathcal{O}_{\mathbb{P}_{1}}(1)\right|_{C^{\prime}}\right) \otimes \mathcal{A}^{\vee}$. Hence

$$
2-2 g \leq \operatorname{deg}(\mathcal{B})+(\operatorname{rk}(\mathcal{B})-1) \cdot\left\ulcorner 2 g-\mu_{\min }(\mathcal{B})\right\urcorner+\mu_{\max }\left(\mathcal{A}^{\vee}\right) .
$$

Therefore

$$
\begin{aligned}
2-2 g & \leq \operatorname{deg}(\mathcal{B})+(\operatorname{rk}(\mathcal{B})-1)\left(2 g+1-\mu_{\min }(\mathcal{B})\right)-\mu_{\min }(\mathcal{A}), \\
0 & \leq \operatorname{rk}(\mathcal{B}) \cdot\left(\mu(\mathcal{B})-\mu_{\min }(\mathcal{B})+2 g+1\right)+\mu_{\min }(\mathcal{B})-\mu_{\min }(\mathcal{A}), \text { and } \\
\mu_{\min }(\mathcal{A}) & -\mu_{\min }(\mathcal{B}) \leq r \cdot\left(\mu_{\max }(\mathcal{B})-\mu_{\min }(\mathcal{B})+2 g+1\right) .
\end{aligned}
$$

Let

$$
\mu_{\max }(\tilde{\mathcal{E}})=\mu_{1}>\mu_{2}>\ldots>\mu_{m}=\mu_{\min }(\tilde{\mathcal{E}})
$$

be the slopes of the composition factors in the Harder-Narasimhan filtration of $\tilde{\mathcal{E}}$, so that also $\mu_{\text {min }}(\mathcal{B})=\mu_{m}$.

Put $M_{i}=\mu_{i}-\mu_{m}$. Then we get

$$
M_{i} \leq r \cdot\left(M_{i+1}+2 g+1\right),
$$

which leads by descending induction on $i$ to

$$
M_{1} \leq\left(r^{r}-1\right) r(2 g+1) /(r-1),
$$

as stated.
9.1.3.4 Remark. This bound is clearly crude. Its virtue, however, is that it is independent of $p$.
9.1.3.5 Proposition. $\mathcal{F}$ is $p$-closed if $p \gg 0$.

Proof. $\mu\left(\left.F^{*} \mathcal{F}\right|_{C}\right)=p \cdot \mu\left(\left.\mathcal{F}\right|_{C}\right) \geq p$. Then if $p \gg 0$, we have, by (9.1.3.3), $\mu_{\min }\left(\left.F^{*} \mathcal{F}\right|_{C}\right)>\mu_{\max }\left(\left.\mathcal{G}\right|_{C}\right)$. Hence $\operatorname{Hom}_{\mathcal{O}_{X}}\left(F^{*} \mathcal{F}, \mathcal{G}\right)=0$ for $p \gg 0$.

Now let $\rho: X \rightarrow Y=X / \mathcal{F}$ be the quotient by $\mathcal{F}(p \gg 0)$. There is $G \in \operatorname{Pic} Y$ such that $\rho^{*} G=p H$, and $G$ is ample. By (9.1.2.3),

$$
C \cdot \rho^{*} c_{1}(Y)=p \cdot\left(C \cdot c_{1}(\mathcal{F})\right)+\left(C \cdot c_{1}(\mathcal{G})\right)
$$

$\operatorname{Put}\left(C \cdot c_{1}(\mathcal{F})\right)=\gamma$. For all $\beta$ with $0<\beta<\gamma$, we have $\left(C \cdot \rho^{*} c_{1}(Y)\right) \geq \beta \cdot p$ for $p \gg 0$. Let $f: C \rightarrow Y$ be the composite. Then

$$
\operatorname{dim}_{[f]} \operatorname{Mor}(C, Y) \geq \beta \cdot p+n(1-g),
$$

so that for every $b \in \mathbb{N}$ with $\beta \cdot p+n(1-g)-b n>0$ and for every subscheme $B \subset C$ of length $b$, we can deform $f$ nontrivially, keeping $B$ fixed.

Then by [Miyaoka-Mori86, Theorem 4], through a general point of $f(C)$ there is a rational curve $L$ such that

$$
G \cdot L \leq 2 \operatorname{deg}\left(f^{*} G\right) /(\beta p-g)
$$

(N.B. [Miyaoka-Mori86, Theorem 4] is stated for morphisms $f: C \rightarrow X$ where $X$ is projective and smooth. However, the proof given there carries over verbatim to the case where $X$ is allowed to be singular, provided that $f(C)$ lies in the smooth locus of $X$.)

Hence for any $\alpha$ with $0<\alpha<\beta$, we have

$$
L \cdot G \leq 2 n \cdot \operatorname{deg}\left(f^{*} G\right) / \alpha p=2 n(C \cdot H)
$$

independently of $p$ (provided that $p \gg 0$ ).
Since $\rho$ is purely inseparable, $L$ pulls back to give a rational curve $M$ through a general point $x$ of $X$.
9.1.3.6 Lemma. $M \rightarrow L$ is purely inseparable.

Proof. If not, then $M \rightarrow L$ is birational. Then

$$
p(M \cdot H)=M \cdot \rho^{*} G=L \cdot G \leq 2 n(C \cdot H) / \alpha .
$$

This is absurd for $p \gg 0$.
9.1.3.7 Lemma. $M \cdot H \leq 2 n(H \cdot C) / \alpha$.

Proof. By (9.1.3.6), $p(M \cdot H)=M \cdot \rho^{*} G=p(L \cdot G)$. Then $M \cdot H \leq 2 n(C$. $H) / \alpha$.

### 9.1.4 Conclusion of proof of ( $\mathbf{9 . 0 . 2}$ (bis))

By (9.1.3.7) and the properties of the Hilbert scheme, through a general point $x$ of $X$ (in characteristic zero) there is a rational curve $M$ with $M \cdot H \leq 2 n(C \cdot H) / \alpha$.

This holds for all $\alpha$ with $0<\alpha<C \cdot c_{1}(\mathcal{F})$, and so

$$
M \cdot H \leq 2 n(C \cdot H) /\left(C \cdot c_{1}(\mathcal{F})\right)
$$

The final thing to check is that $T_{M}(x) \hookrightarrow \mathcal{F}(x)$ for general $x \in M$. This can be checked after reduction modulo $p$, for all $p \gg 0$, and now it is equivalent to (9.1.3.6)

### 9.1.5 Proof of (9.0.2).

Given $\mathcal{E} \hookrightarrow T_{X}$ with $c_{1}(\mathcal{E}) \cdot C>0$, we certainly have $\mu_{\max }\left(\left.T_{X}\right|_{C}\right)>0$. Hence we can take as $\mathcal{F}$ any term in the Harder- Narasimhan filtration of $T_{X}$ such that $\mu_{\text {min }}\left(\left.\mathcal{F}\right|_{C}\right)>0$.

### 9.1.6 Compactifying the leaves of $\mathcal{F}$.

The classical theorem of Frobenius et al. shows that, given $\mathcal{F} \hookrightarrow T_{X}$ closed under Lie bracket, the leaves of $\mathcal{F}$ exist locally analytically away from the singularities of $X$ and of $\mathcal{F}$. That is, locally analytically there is a morphism $\rho: X \rightarrow Y$ with $\mathcal{F}=\operatorname{ker} d \rho$. In general the leaves are not compact; however, we now show (9.0.3) which says that if $\mathcal{F}$ is positive in the above sense of Miyaoka, then the rational curves that have been constructed tangent to $\mathcal{F}$ can be bundled together to give compact leaves of $\mathcal{F}$.
Proof of (9.0.3). Consider the family $\left\{M_{t}\right\}$ of rational curves tangent to $\mathcal{F}$ constructed above. Pick a geometric generic point $\xi$ of $X$. Define inductively an ascending chain of subvarieties $V_{i}$ of $X$, as follows:
$V_{0}=\{\xi\}$, and for $i>0 V_{i}$ is an irreducible component of the scheme swept out by those curves $M_{t}$ passing through a general point of $V_{i-1}$.

Let $m$ denote the least value of $i$ such that $V_{i}=V_{i+1}$, and put $V_{m}=V$.

### 9.1.6.1 Lemma. $V$ is tangent at its generic point to $\mathcal{F}$.

Proof. $V$ is covered by curves $M_{t}$, so that if $\eta$ is a geometric generic point of $V$ the generic curve $M_{t}$ through $\eta$ is smooth there, and the tangent lines $T_{M_{t}}(\eta)$ sweep out a Zariski open subset of the tangent space $T_{V}(\eta)$. Since $T_{M_{t}}(\eta) \subset \mathcal{F}(\eta)$ for all $t$, it follows that $T_{V}(\eta) \subset \mathcal{F}(\eta)$ also, as stated.
9.1.6.2 Lemma. There is a rational map $\sigma: X \rightarrow Z$ such that $\operatorname{dim} Z<$ $\operatorname{dim} X$ and $\operatorname{ker} d \sigma(\xi) \subset \mathcal{F}(\xi)$.

Proof. By construction, there is a unique subvariety $V$ as described above passing through $\xi$. Since the Hilbert scheme of $X$ has only countably many components and the field $\mathbb{C}$ is uncountable, there is an irreducible algebraic family of subvarieties $\left\{V_{z}\right\}_{z \in Z}$ in $X$ that covers $X$, with the property that there is a unique member $V$ through $\xi$. Hence there is a rational map $\sigma$ : $X \rightarrow Z$ sending each point to the subvariety through it. By (9.1.5.1) we have ker $d \sigma(\xi) \subset \mathcal{F}(\xi)$, as required.

Consider the map $\sigma: X \rightarrow Z$, and say that $\operatorname{dim} X-\operatorname{dim} Z=r$. If ker $d \sigma=\mathcal{F}$ at $\xi$, then there is nothing to do. If not, then there is an exact sequence

$$
0 \rightarrow \mathcal{A} \rightarrow \sigma^{*} T_{Z} \rightarrow \mathcal{G} \rightarrow 0
$$

where $\mathcal{A}=\mathcal{F} / \operatorname{ker} d \sigma$ and $\mathcal{G}=T_{X} / \mathcal{F}$.
Define $W=D_{1} \cap \ldots \cap D_{m}$, where $D_{i} \in\left|m_{i} H_{i}\right|$ is general, so that $W$ is generically finite over $Z$ and $\mu_{\min }\left(\left.\mathcal{A}\right|_{W}\right)>\max \left\{\mu_{\max }\left(\left.\mathcal{G}\right|_{W}\right), 0\right\}$. Let $Q$ be the Galois closure of $W \rightarrow Z$ and let $\mathcal{L}$ (resp. $\mathcal{M}$ ) be the pull-back of $\left.\mathcal{A}\right|_{W}$ (resp. $T_{Z}$ ) to $Q$. It is clear from consideration of the slopes of these sheaves (restricted to the inverse image of $C$ ) that $\mathcal{L}$ is a Galois invariant subsheaf of $\mathcal{M}$. Hence $\mathcal{A}$ descends to a subsheaf $\mathcal{H}$ of $T_{Z}$ and the curves $\left\{C_{t}\right\}$ form a covering family of curves on $Z$ whose general member misses any given codimension two subset of $Z$ such that, letting $f: C \rightarrow Z$ be the composite of $C \hookrightarrow X \rightarrow Z$, we have $\mu_{\min }\left(f^{*} \mathcal{H}\right)>\max \left\{\mu_{\max }\left(f^{*}\left(T_{Z} / \mathcal{H}\right)\right), 0\right\}$.

We can now follow (9.1.3) and (9.1.4) to find rational curves on $Z$ that are tangent to $\mathcal{H}$, so that a trivial inductive argument completes the proof of (9.0.3).
9.1.7 (9.1.3.3) allowed us to avoid the following issue. Suppose that $X$ is a normal (or smooth) $n$-dimensional projective variety in char. $p>0$ and that $\mathcal{E}$ is a reflexive (or locally free) sheaf on $X$ of rank $r \leq n$. Then it seems likely that for $\mathcal{E}$ to be semistable while $F^{*} \mathcal{E}$ is unstable should impose strong conditions on $X$; e.g., maybe $X$ should be uniruled. The exact meaning of stability here is deliberately unclear, but when $r=n=2$ and instability is taken in Bogomolov's sense, then results along these lines have been established and used in [Shepherd-Barron91]. However, when $n \geq r \geq 2$ this is not known.

### 9.2 The nonnegativity of the Kodaira dimension for regular minimal threefolds

Throughout this section, $X$ will denote a minimal threefold of index $r$ and irregularity $q(X)=0$. $X$ has isolated singularties. We shall fix a resolution

## N. SHEPHERD-BARRON

$\rho: Y \rightarrow X$ such that $\rho^{-1}$ is an isomorphism over the smooth locus $X^{0}$ of $X$. Our aim is to prove (9.0.6), so that we may assume that $p_{g}(X)=0$. Hence $\chi\left(\mathcal{O}_{X}\right) \geq 1$.
Theorem 9.3. (i) $c_{2}(Y) \cdot \rho^{*} H \geq 0$. (That is, $c_{2}(Y)$ is pseudo-effective.)
(ii) $c_{2}(Y) \cdot \rho^{*} D \geq 0$ for all nef $\mathbb{Q}$-divisors $D$ on $X$.

Proof. (i) Put $\mathcal{F}=\left(\rho_{*} \Omega_{Y}^{1}\right)^{\vee \vee}$. Since $X$ is not uniruled, by the main result of [Miyaoka-Mori86], (9.0.1) shows that $\mathcal{F}$ is generically semipositive, while $c_{1}(\mathcal{F})$ is nef by definition. It is shown in (10.12) that now $c_{2}(Y) \cdot \rho^{*} H \geq 0$, as required.
(ii) $D$ is a limit of ample divisors, so that (ii) follows from (i).

Recall the Riemann-Roch formula, where $n \equiv 0(\bmod r)$ :

$$
\begin{aligned}
& \chi\left(Y, \rho^{*} \mathcal{O}\left(n K_{X}\right)\right) \\
& \quad=\frac{2 n^{3}-3 n^{2}}{12}\left(\rho^{*} K_{X}\right)^{3}+\frac{n}{12}\left(\rho^{*} K_{X}\right) \cdot\left(K_{Y}^{2}+c_{2}(Y)\right)+\chi\left(\mathcal{O}_{X}\right) \\
& \quad=\frac{2 n^{3}-3 n^{2}}{12} K_{X}^{3}+\frac{n}{12} K_{X} \cdot\left(K_{X}^{2}+\rho_{*} c_{2}(Y)\right)+\chi\left(\mathcal{O}_{X}\right) \\
& \quad \geq \chi\left(\mathcal{O}_{X}\right) \geq 1
\end{aligned}
$$

Proof of (9.0.6). We shall consider various cases separately:
(1) $K_{X}^{2} \not \equiv 0$.
(2) $K_{X} \not \equiv 0, K_{X}^{2} \equiv 0$ and $\pi_{1}^{a l g}\left(X^{0}\right)$ is finite ( $X^{0}$ being the smooth locus of $X$ ).
(3) $K_{X} \not \equiv 0, K_{X}^{2} \equiv 0$ and $\pi_{1}^{a l g}\left(X^{0}\right)$ is infinite.
(4) $K_{X} \equiv 0$.

Case (1): Fix a smooth ample divisor $H$ on $X$. Taking cohomology of

$$
0 \rightarrow \mathcal{O}\left(n K_{X}\right) \rightarrow \mathcal{O}\left(n K_{X}+H\right) \rightarrow \mathcal{O}_{H}\left(n K_{X}+H\right) \rightarrow 0
$$

gives an exact sequence

$$
\begin{aligned}
H^{1}\left(X, \mathcal{O}\left(n K_{X}+H\right)\right) & \rightarrow H^{1}\left(H, \mathcal{O}_{H}\left(n K_{X}+H\right)\right) \\
& \rightarrow H^{2}\left(X, \mathcal{O}\left(n K_{X}\right)\right) \rightarrow H^{2}\left(X, \mathcal{O}\left(n K_{X}+H\right)\right)
\end{aligned}
$$

If $H$ is sufficiently ample, then the first and last terms vanish, giving

$$
H^{1}\left(H, \mathcal{O}_{H}\left(n K_{X}+H\right)\right) \cong H^{2}\left(X, \mathcal{O}\left(n K_{X}\right)\right)
$$

Assume that these groups are nonzero; then Serre duality on $H$ gives

$$
H^{1}\left(H, \mathcal{O}_{H}\left(-(n-1) K_{X}\right)\right) \neq 0
$$

However, $\mathcal{O}_{H}\left(K_{X}\right)$ is nef and big, so that by the Kodaira-Ramanujam vanishing theorem $H^{1}\left(H, \mathcal{O}_{H}\left(-(n-1) K_{X}\right)\right)=0$.

Hence $H^{2}\left(X, \mathcal{O}\left(n K_{X}\right)\right)=0$. Since $R^{i} \rho_{*} \mathcal{O}_{Y}=0$ for $i>0$, we get that $H^{2}\left(Y, \rho^{*} \mathcal{O}\left(n K_{X}\right)\right)=0$, and R-R. gives $P_{n}(Y)=P_{n}(X) \geq 1$.

Case (2): Let $\sigma: \tilde{X} \rightarrow X$ be the finite cover inducing the universal algebraic cover of $X^{0}$, with $\tilde{X}$ normal. $K_{\tilde{X}}=\sigma^{*} K_{X}$, thus $\tilde{X}$ is minimal, and it is enough to show that $\kappa(X) \geq 0$. Hence we may assume that $\pi_{1}^{a l g}\left(X^{0}\right)=1$.

Again let $H$ be a smooth ample divisor on $X$. Then $\pi_{1}^{a l g}(H)=1$, by [Grothendieck68]. As in case (1), we can assume that $H^{2}\left(X, \mathcal{O}\left(n K_{X}\right)\right) \neq 0$. So by Serre duality, there is a nonsplit extension

$$
0 \rightarrow \mathcal{O}\left(K_{X}\right) \rightarrow \mathcal{E} \rightarrow \mathcal{O}\left(n K_{X}\right) \rightarrow 0
$$

Assume that $\mathcal{E}$ is $H$-stable. Then if $\operatorname{deg} H \gg 0,\left.\mathcal{E}\right|_{H}=\mathcal{F}$, say, is $H$ stable. Consider $\mathcal{F} \otimes \mathcal{F}^{\vee}=$ End $\mathcal{F}=\mathcal{G}$, say. $\mathcal{G}$ is polystable (i.e., a direct sum of stable bundles of the same slope). We have $c_{1}(\mathcal{G})=0$ and $c_{2}(\mathcal{G})=4 c_{2}(\mathcal{F})-c_{1}(\mathcal{F})^{2}=0$, since $K_{X}^{2} \cdot H=0$. Then by a theorem of [Donaldson85], $\mathcal{G}$ is induced from a representation of $\pi_{1}(H)$. Since $\pi_{1}^{a l g}(H)=1$ and finitely generated subgroups of complex linear groups are residually finite, this representation is trivial. That is, $\mathcal{G}$ is trivial. Hence $H^{0}($ End $\mathcal{F})=4$, so that, by the Cayley-Hamilton theorem, $\mathcal{F}$ has a nonzero nilpotent endomorphism. This, however, contradicts the $H$-stability of $\mathcal{F}$.

Hence $\mathcal{E}$ is not $H$-stable. So there is an exact sequence

$$
0 \rightarrow \mathcal{A} \rightarrow \mathcal{E} \rightarrow \mathcal{B} \rightarrow 0
$$

which destabilizes $\mathcal{E}$; then the composite arrows $\mathcal{A} \rightarrow \mathcal{O}(n K)$ and $\mathcal{O}(K) \rightarrow \mathcal{B}$ are nonzero.

We have $\mathcal{A}^{\vee \vee}=\mathcal{O}(A)$ and $\mathcal{B}^{\vee \vee}=\mathcal{O}(B)$ with $A, B$ Weil divisors on $X$. Put $\left.A\right|_{H}=a,\left.B\right|_{H}=b,\left.H\right|_{H}=h$ and $\left.K_{X}\right|_{H}=k$. We obtain that $a+b=(n+1) k, h \cdot(a-b) \geq 0$ and $a \cdot b \leq n \cdot k^{2}=0$.

Suppose that $(a-b)^{2}>0$. Then $(a-b) \in C_{++}(H)$, the positive cone of $H$, so that $h^{0}(\mathcal{O}(m(a-b)))=O\left(m^{2}\right)$ for $m \gg 0$. Since $b-k$ and $n k-a$ are effective, we get

$$
h^{0}(\mathcal{O}(m(n-1) k))=O\left(m^{2}\right) \quad \text { for } \quad m \gg 0
$$

However, $k$ is nef and $k^{2}=0$, so this is impossible. Hence $(a-b)^{2}=0$.
Since $\mathcal{O}(a) \hookrightarrow \mathcal{O}(n k)$ and $\mathcal{O}(k) \hookrightarrow \mathcal{O}(b)$, we get $\mathcal{O}(a-b) \hookrightarrow \mathcal{O}((n-1) k)$. Since $k^{2}=0$ and $k$ is nef, we find $k \cdot(a-b)=0$. Since $k$ and $a-b$ both lie in the closure of $C_{++}(H)$, the index theorem gives $\mathbb{Q} \cdot k=\mathbb{Q} \cdot(a-b)$
in $\operatorname{NS}(H) \otimes \mathbb{Q}$. Since $\pi_{1}^{a l g}(H)=1$ and $\operatorname{Weil}(X) \hookrightarrow \operatorname{Pic}(H)$, it follows that $\mathbb{Q} \cdot K_{X}=\mathbb{Q} \cdot(A-B)$ in $\operatorname{Weil}(X) \otimes \mathbb{Q}$.

There is a primitive element $D \in \operatorname{Weil}(X)$ such that $A \sim \alpha D, B \sim \beta D$ and $K_{X} \sim \kappa D$ for some $\alpha, \beta, \kappa \in \mathbb{Z}$. Since $\mathcal{O}(A) \hookrightarrow \mathcal{O}\left(n K_{X}\right)$ we obtain that $h^{0}(\mathcal{O}(n \kappa-\alpha) D)>0$, hence $P_{n \kappa-\alpha}(X)>0$.

Case (3): By the proof of (6.7.2) $\pi_{1}^{\text {alg,loc }}(X, P)$ is finite. (This is actually true for any isolated 3 -fold canonical singularity.) Hence finite étale Galois covers $\tilde{X}^{0}$ of $X^{0}$ of sufficiently high degree extend to varieties $\tilde{X}$ that factorize as

$$
\tilde{X} \xrightarrow{\beta} X_{1} \xrightarrow{\alpha} X
$$

where $\alpha$ is of bounded degree and is étale over $X^{0}, X_{1}$ is minimal and $\beta$ is étale.

Since it is enough to show that $\kappa\left(X_{1}\right) \geq 0$, we may assume that $X=X_{1}$, i.e., that $\pi_{1}^{a l g}(X)$ is infinite. Also, we may assume that all these finite covers are regular, since irregular minimal 3 -folds are known to have $\kappa \geq 0$.

Replacing $X$ by $\tilde{X}$, we can assume that $\chi\left(\mathcal{O}_{X}\right) \geq 4$. Fixing a resolution $\rho: Y \rightarrow X$, we get $h^{0}\left(\Omega_{Y}^{2}\right) \geq 3$. Choosing three linearly independent sections in $H^{0}\left(\Omega_{Y}^{2}\right)$, we get a homomorphism $\gamma: \mathcal{O}_{Y}^{3} \rightarrow \Omega_{Y}^{2}$. Say rank $\gamma=r$, and let $\mathcal{E}$ denote im $\gamma$. Since $\Omega_{Y}^{2} \otimes \mathcal{O}\left(-K_{Y}\right) \cong T_{Y}$, Theorem 1 gives

$$
\left(c_{1}(\mathcal{E})-r K_{Y}\right) \cdot \rho^{*} H \cdot \rho^{*} L \leq 0
$$

for all ample $H, L \in \operatorname{Pic}(X) \otimes \mathbb{Q}$. Since $K_{Y} \cdot \rho^{*} H \cdot \rho^{*} L=K_{X} \cdot H \cdot L$, we see, letting $L \rightarrow K_{X}$, that

$$
c_{1}(\mathcal{E}) \cdot \rho^{*} H \cdot \rho^{*} K_{X} \leq r H \cdot K_{X}^{2}=0
$$

since $K_{X}^{2} \equiv 0$. But $c_{1}(\mathcal{E})$ is effective, and so

$$
c_{1}(\mathcal{E}) \cdot \rho^{*} K_{X} \cdot \rho^{*} H=0 .
$$

Since $h^{0}\left(\mathcal{O}\left(c_{1}(\mathcal{E})\right)\right) \geq 3$, we can write $\left|c_{1}(\mathcal{E})\right|=B+|M|$, where $|M|$ has no fixed component and $\operatorname{dim}|M| \geq 2$. We get $M \cdot \rho^{*} K_{X} \cdot \rho^{*} H \geq 0$.

Suppose that $H$ is sufficiently ample and that $S$ is a general member of $\left|\rho^{*} H\right|$. Then by the Hodge index theorem on $S$, we get $\left.\mathbb{Q} \cdot M\right|_{S}=\mathbb{Q} \cdot\left(\rho^{*} K_{X}\right)$ in $\mathrm{NS}(S) \otimes \mathbb{Q}$. Since $q(X)=0$, it follows that $m \cdot \rho_{*} M \sim n \cdot K_{X}$ for some $m, n \in \mathbb{N}$, and so $\kappa(X) \geq 0$.

Case (4): Since $q(X)=0$, we have $|\operatorname{TorsPic}(X)| \cdot r K_{X} \sim 0$, and so $\kappa(X) \geq$ 0.

## 10. CHERN CLASSES OF Q-SHEAVES

Gábor Megyesi

In this chapter we introduce the notions of $Q$-varieties, $Q$-sheaves, Chern classes for $Q$-sheaves, and we extend some results, such as the condition for semistability and the Bogomolov-Miyaoka-Yau inequality $c_{1}^{2} \leq 3 c_{2}$, from smooth varieties to $Q$-varieties. One of our main aims is to calculate the Chern classes of the $Q$-sheaves of $\log$ differentials. Kawamata's original approach was more analytic, using Chern forms; we take a different, algebraic approach. This also enables us to define Chern classes for $Q$-sheaves in general, not just $Q$-vector bundles.

We work over an algebraically closed field of characteristic 0 throughout.
10.1 Definition. [Mumford83, §2.] A $Q$-variety is an irreducible, normal, quasiprojective algebraic variety $X$ with only quotient singularities, together with a finite atlas of charts

$$
\left.p_{\dot{\alpha}}\right|_{U_{\alpha}} ^{X_{\alpha}}{\underset{\alpha}{\alpha}}_{\searrow}^{X_{\alpha}^{\prime} / G_{\alpha}^{\prime}}
$$

where $U_{\alpha}$ is a Zariski open subset of $X, X=U_{\alpha} U_{\alpha}, p_{\alpha}^{\prime}$ is étale, quasifinite, Galois, surjective, and finite in a neighbourhood of any singular point, $X_{\alpha}$ is smooth and quasiprojective, $G_{\alpha}$ is a finite group acting faithfully on $X_{\alpha}$, freely in codimension one, so that $X_{\alpha} \rightarrow X_{\alpha} / G_{\alpha}$ is finite, Galois and étale in codimension 1 . We also require the compatibility condition that the natural projections from the normalisation $X_{\alpha \beta}$ of $X_{\alpha} \times_{X} X_{\beta}$ to $X_{\alpha}$ and $X_{\beta}$ should be étale.
$X$ can also be constructed globally as the quotient of a quasiprojective variety $\tilde{X}$ by a finite group. Take a Galois extension of the function field $k(X)$ containing all the function fields $k\left(X_{\alpha}\right)$, and let $\tilde{X}$ be the normalisation of $X$ in this field. Then $G=\operatorname{Gal}(k(\tilde{X}) / k(X))$ acts faithfully on $\tilde{X}$, and $X=\tilde{X} / G$.

Let $p$ be the projection morphism $p: \tilde{X} \rightarrow X$, and $\tilde{X}_{\alpha}=p^{-1}\left(U_{\alpha}\right)$. We have the following diagram

where $\tilde{X}_{\alpha}$ is open in $\tilde{X}, H_{\alpha}^{\prime} \leq G$ is the stabilizer of $\tilde{X}_{\alpha}$ as a set, $H_{\alpha} \triangleleft H_{\alpha}^{\prime}$ with $G_{\alpha}=H_{\alpha}^{\prime} / H_{\alpha}$.

This global cover $\tilde{X}$ constructed above need not be smooth in general. However, in the case most important for us, that of surfaces, $\tilde{X}$ is always Cohen-Macaulay, because a normal surface is Cohen-Macaulay; we need this fact later.
10.2 Definition. (cf. [Mumford83, §2.]) A $Q$-sheaf on a $Q$-variety $X$ is a coherent sheaf on $X$ together with a collection of $G_{\alpha}$-linearized coherent sheaves $\mathcal{F}_{\alpha}$ on the $X_{\alpha}$, such that $p_{\alpha}^{\prime *}\left(\left.\mathcal{F}\right|_{U_{\alpha}}\right)=\mathcal{F}_{\alpha}^{G_{\alpha}}$, with isomorphisms $\mathcal{F}_{\alpha} \otimes \mathcal{O}_{X_{\alpha}} \mathcal{O}_{X_{\alpha \beta}} \cong \mathcal{F}_{\beta} \otimes_{\mathcal{O}_{X_{\beta}}} \mathcal{O}_{X_{\alpha \beta}}$, satisfying the natural compatibility conditions on triple overlaps. The $\mathcal{F}_{\alpha}$ pull back to coherent sheaves on the $\tilde{X}_{\alpha}$ with compatible $H_{\alpha}^{\prime}$ actions, so they glue together to a coherent sheaf $\tilde{\mathcal{F}}$ on $\tilde{X}$ with $G$ action, and $\mathcal{F}=\tilde{\mathcal{F}}^{G}$.
$\mathcal{F}$ is $Q$-locally free or a $Q$-vector bundle if all the $\mathcal{F}_{\alpha}$ are locally free. A sequence $\mathcal{E} \rightarrow \mathcal{F} \rightarrow \mathcal{G}$ of $Q$-sheaves is said to be $Q$-exact if the corresponding sequence $\mathcal{E}_{\alpha} \rightarrow \mathcal{F}_{\alpha} \rightarrow \mathcal{G}_{\alpha}$ is exact on each $X_{\alpha}$.

A subvariety $Y$ of a $Q$-variety $X$ need not be a $Q$-variety in a way compatible with the $Q$-variety structure of $X$; even if $Y$ is smooth and irreducible, its cover $Y_{\alpha}=p_{\alpha}^{-1}\left(\left.Y\right|_{U_{\alpha}}\right) \subset X_{\alpha}$ may be singular or disconnected. $Y$ is still the quotient of $Y_{\alpha}$ by $G_{\alpha}$; the group action, however, need not be free in codimension 1 any more. Considering the reduced scheme structure on the $Y_{\alpha}$, the $\mathcal{O}_{\left(Y_{\alpha}\right)_{\text {red }}}$ define a $Q$-sheaf structure on $\mathcal{O}_{Y}$. We can define a $Q$-sheaf on $Y$ to be a coherent sheaf $\mathcal{F}$ on $Y$ together with a collection of coherent sheaves $\mathcal{F}_{\alpha}$ on the $Y_{\alpha}$ with a $G_{\alpha}$ action, such that $\left.\mathcal{F}\right|_{Y \cap U_{\alpha}}=\mathcal{F}_{\alpha}^{G_{\alpha}}$ and the $\mathcal{F}_{\alpha}$ satisfy the same compatibility condition as required for a $Q$-sheaf on $X$.
10.3 Examples. (i) $\mathcal{F}=\hat{\Omega}_{X}^{1}$ is a $Q$-sheaf, with $\mathcal{F}_{\alpha}=\Omega_{X_{\alpha}}^{1}$.
(ii) If $X$ is a surface with quotient singularities and $C \subset X$ is a curve, then $\mathcal{I}_{C}=\mathcal{O}(-C)$ can be given a $Q$-vector bundle structure by setting
$\mathcal{F}_{\alpha}=\left(\mathcal{I}_{q_{U_{\alpha}}} \cdot \mathcal{O}_{X_{\alpha}}\right)^{\vee \vee}$. There is also a short $Q$-exact sequence of $Q$-sheaves $0 \rightarrow \mathcal{O}(-C) \rightarrow \mathcal{O} \rightarrow \mathcal{O}_{C} \rightarrow 0$.
(iii) If $(X, B)$ is a $\log$ canonical surface, where $X$ has only quotient singularities, then $\hat{\Omega}_{X}^{1}(\log B)$ exists as a $Q$-vector bundle. Let $C_{\alpha}=p_{\alpha}^{-1}\left(\left.B\right|_{U_{\alpha}}\right)$. By the classification of Chapter 3, there are three possibilities in the neighbourhood of a point of $C_{\alpha}$.
(a) $\left(X_{\alpha}, C_{\alpha}\right)$ is analytically isomorphic to ( $\left.\mathbb{A}^{2}, x=0\right), G_{\alpha} \cong \mathbb{Z}_{n}$ acting by $(x, y) \rightarrow\left(\zeta x, \zeta^{a} y\right)$, where $\zeta$ is a primitive $n$-th root of unity, $(a, n)=1$,
(b) $\left(X_{\alpha}, C_{\alpha}\right) \cong\left(\mathbb{A}^{2}, x y=0\right), G_{\alpha} \cong \mathbb{Z}_{n}$ acting by $(x, y) \rightarrow\left(\zeta x, \zeta^{a} y\right)$, or
(c) $\left(X_{\alpha}, C_{\alpha}\right) \cong\left(\mathbb{A}^{2}, x y=0\right), G_{\alpha}$ is the binary dihedral group of order $4 n$ acting by $(x, y) \rightarrow\left(\zeta x, \zeta^{a} y\right)$ and $(x, y) \rightarrow(-y, x)$.
In each case $C_{\alpha}$ has normal crossings, therefore $\mathcal{F}_{\alpha}=\Omega_{X}^{1}\left(\log C_{\alpha}\right)$ is a locally free sheaf, so $\hat{\Omega}_{X}^{1}(\log B)$ is $Q$-locally free.

Considering the normalization $C_{\alpha}^{\nu}$ of $C_{\alpha}$, we see that the $G_{\alpha}$ action extends naturally to $\mathcal{O}_{C_{\alpha}^{\nu}}$. Therefore we can define the $Q$-sheaf $\mathcal{O}_{B^{\nu}}$, the $Q$ normalisation of $B$, by the collection of sheaves $\mathcal{O}_{C_{\alpha}^{\nu}}$ on the $X_{\alpha}$. If $B_{1}, \ldots, B_{s}$ are the components of $B$, then $\mathcal{O}_{B^{\nu}}=\bigoplus_{i=1}^{s} \mathcal{O}_{B_{i}^{\nu}}$, and we have a $Q$-exact sequence

$$
0 \rightarrow \hat{\Omega}_{X}^{1} \rightarrow \hat{\Omega}_{X}^{1}(\log B) \rightarrow \bigoplus_{i=1}^{s} \mathcal{O}_{B_{i}^{\nu}} \rightarrow 0
$$

whose $Q$-exactness follows from the exactness of

$$
0 \rightarrow \Omega_{X_{\alpha}}^{1} \rightarrow \Omega_{X_{\alpha}}^{1}\left(\log C_{\alpha}\right) \rightarrow \mathcal{O}_{C_{\alpha}^{\nu}} \rightarrow 0
$$

For any quasiprojective variety $Z$ we can define the Chow ring $A_{*}(Z)=$ $\oplus_{k=0}^{\operatorname{dim} Z} A_{k}(Z)$, where $A_{k}$ is the group of $k$ dimensional cycles on $Z$ modulo rational equivalence, and for $Y$ smooth, we can also define $A^{*}(Y)=$ $\oplus_{k=0}^{\operatorname{dim} Y} A^{k}(Y)$, where $A^{k}$ is the group of $k$ codimensional cycles on $Y$ modulo rational equivalence. A morphism $h: Z \rightarrow Y$ induces a cap product $A^{k}(Y) \times A_{l}(Z) \xrightarrow{\cap} A_{l-k}(Z),[$ Fulton75, §2].
10.4 Definition. For $V$ a possibly singular quasiprojective variety, we define

$$
A^{*}(V)=\operatorname{Im}\left\{\lim _{f: V \rightarrow Y} A^{*}(Y) \rightarrow \prod_{g: Z \rightarrow V} \operatorname{End}\left(A_{*}(Z)\right)\right\}
$$

where $Y, Z$ are quasiprojective, $Y$ is smooth, and the map is induced by the cap product (cf. [Fulton75, §2.] or the definition of $o p A^{\circ}$ in [Mumford83, §1.]).

This definition agrees with the original one for $V$ smooth. Moreover, $A^{*}$ is a contravariant functor, $A^{*}(V)$ inherits a natural ring structure, cap products
can be defined, and most importantly for our purposes, for any coherent sheaf $\mathcal{F}$ on $V$ with finite locally free resolution, we can define Chern classes $c_{k}(\mathcal{F}) \in A^{k}(V)$ [Fulton75, §3.2].

In some of the following we need that $\tilde{X}$ is Cohen-Macaulay, therefore we assume it from now on. As remarked above, this assumption is satisfied for surfaces. The following lemma explains its significance.
10.5 Lemma. [Mumford83, Proposition 2.1.] If $X$ is quasi projective and $\tilde{X}$ is Cohen-Macaulay, then any coherent sheaf $\tilde{\mathcal{F}}$ on $\tilde{X}$ arising from a $Q$-sheaf $\mathcal{F}$ on $X$ has a finite locally free resolution.
Proof. Let $n=\operatorname{dim} X$. Let $0 \rightarrow \tilde{\mathcal{E}}_{n} \rightarrow \tilde{\mathcal{E}}_{n-1} \rightarrow \ldots \rightarrow \tilde{\mathcal{E}}_{1} \rightarrow \tilde{\mathcal{E}}_{0} \rightarrow \tilde{\mathcal{F}}$ be a resolution of $\tilde{\mathcal{F}}$, with $\tilde{\mathcal{E}}_{0}, \tilde{\mathcal{E}}_{1}, \ldots, \tilde{\mathcal{E}}_{n-1}$ locally free $\mathcal{O}_{\tilde{X}}$-modules. As $X_{\alpha}$ is smooth, $\mathcal{F}_{\alpha}$ has a locally free resolution of length at most $n$. The morphism $\tilde{X}_{\alpha} \rightarrow X_{\alpha}$ is flat, since $\tilde{X}_{\alpha}$ is Cohen-Macaulay and $X_{\alpha}$ is smooth, therefore the resolution of $\mathcal{F}_{\alpha}$ pulls back to a locally free resolution of $\left.\tilde{\mathcal{F}}\right|_{\tilde{X}_{\alpha}}$ of length at most $n$. By Schanuel's lemma, if $\left.\tilde{\mathcal{F}}\right|_{\tilde{X}_{\alpha}}$ has a locally free resolution of length at most $n$, then $\left.\tilde{\mathcal{E}}_{0}\right|_{\tilde{X}_{\alpha}},\left.\tilde{\mathcal{E}}_{1}\right|_{\tilde{\mathcal{X}}_{\alpha}}, \ldots,\left.\tilde{\mathcal{E}}_{n-1}\right|_{\tilde{X}_{\alpha}}$ locally free implies that $\left.\tilde{\mathcal{E}}_{n}\right|_{\tilde{X}_{\alpha}}$ is also locally free. Hence $\tilde{\mathcal{E}}_{n}$ is locally free and so $\tilde{\mathcal{F}}$ has a finite locally free resolution.

Hence for any coherent sheaf on $\tilde{X}$ we can define Chern classes in $A^{*}(\tilde{X})$, and using this we can define Chern classes for $Q$-sheaves on $X$.
10.6 Definition. The Chern classes $\hat{c}_{k}$ of the $Q$-sheaf $\mathcal{F}$ on $X$ are given by $\hat{c}_{k}(\mathcal{F})=\frac{1}{|G|} c_{k}(\tilde{\mathcal{F}}) \in A^{k}(\tilde{X}) \otimes \mathbb{Q}$.

By [Mumford83, Theorem 3.1] there exist canonical isomorphisms $\gamma$ : $A_{n-k}(X) \otimes \mathbb{Q} \rightarrow A^{k}(\tilde{X})^{G} \otimes \mathbb{Q}$ for $0 \leq k \leq n$, where $n=\operatorname{dim} X$. Identifying the Chow groups via $\gamma, A_{*}(X) \otimes \mathbb{Q}$ obtains a ring structure and we can define Chern classes in it. There exists a degree map deg: $A^{n}(\tilde{X})^{G} \otimes \mathbb{Q} \rightarrow \mathbb{Q}$; to get the correct intersection numbers on $X$ we have to take into account that $p: \tilde{X} \rightarrow X$ has degree $|G|$, so we define $\operatorname{deg}: A_{0}(X) \otimes \mathbb{Q} \rightarrow \mathbb{Q}$ by $\operatorname{deg} Z=\operatorname{deg} \gamma(Z) /|G|$ for $Z \in A_{0}(X) \otimes \mathbb{Q}$. We can define the total Chern class by $\hat{c}(\mathcal{E})=\sum_{k=0}^{n} \hat{c}_{k}(\mathcal{E})$. As a $Q$-exact sequence of $Q$-sheaves $0 \rightarrow \mathcal{E} \rightarrow \mathcal{F} \rightarrow \mathcal{G} \rightarrow 0$ on $X$ pulls back to a short exact sequence of sheaves $0 \rightarrow \tilde{\mathcal{E}} \rightarrow \tilde{\mathcal{F}} \rightarrow \tilde{\mathcal{G}} \rightarrow 0$ on $\tilde{X}$, we have $\hat{c}(\mathcal{F})=\hat{c}(\mathcal{E}) \hat{c}(\mathcal{G})$.

For a $Q$-sheaf on a subvariety of $X$ we can not in general define Chern classes in this way. We need this only in one case, for $Q$-sheaves on a curve $B$ on a surface $X$ with only quotient singularities such that $(X, B)$ is $\log$ canonical; then the cover $C_{\alpha} \subset X_{\alpha}$ is a curve with at most simple nodes as singularities and we can define $\hat{c}_{1}$ for a $Q$-sheaf on $B$.

By considering the sheaves in codimension 1 only, we see that $\hat{c}_{1}\left(\hat{\Omega}_{X}^{1}\right)=$ $K_{X}$, and if $(X, B)$ is $\log$ canonical, then $\hat{c}_{1}\left(\hat{\Omega}_{X}^{1}(\log B)\right)=K_{X}+B$. Calculating $\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}\right)$ and $\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}(\log B)\right)$ is one of the main aims of this chapter. For this, we need the notion of the orbifold Euler number.
10.7 Definition. Let $X$ be a quasiprojective variety with only isolated quotient singularities and let $Y$ be an open or closed subset of $X$. The orbifold Euler number of $Y$ is defined as

$$
e_{o r b}(Y)=e_{\text {top }}(Y)-\sum_{P \in Y \cap S i n g ~}\left(1-\frac{1}{r(P)}\right),
$$

where $e_{\text {top }}$ is the usual topological Euler number and $r(P)$ is the order of the local fundamental group. It should be noted that if $Y$ is closed then $e_{\text {orb }}(Y)$ depends not only on $Y$ but also on the embedding $Y \subset X$. In our case, this does not lead to any confusion.
10.8 Theorem. Let $X$ be a normal projective surface with only quotient singularities, $B$ a reduced Weil divisor on $X$ such that $(X, B)$ is log canonical. Then

$$
\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}(\log B)\right)=e_{o r b}(X \backslash B) .
$$

Proof. First we consider the case $B=\emptyset$ to prove that $\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}\right)=e_{\text {orb }}(X)$.
Fix a projective embedding of $X$. A generic pencil of hyperplane sections has reduced elements only, and its base locus is reduced and disjoint from Sing $X$ and $B$. Blowing up this base locus we obtain a morphism $f: \hat{X} \rightarrow \mathbb{P}^{1}$ with reduced fibres. Since both sides of the required equality increase by 1 under blowing up a smooth point, we may assume that in fact we have a morphism from $X, f: X \rightarrow \mathbb{P}^{1}$ with reduced fibres. Let $g$ be the genus of the general fiber.

There exists a $Q$-exact sequence

$$
\begin{equation*}
0 \rightarrow f^{*} \Omega_{\mathbb{P}^{1}}^{1} \rightarrow \hat{\Omega}_{X}^{1} \rightarrow \hat{\omega}_{X / \mathbb{P}^{1}} \rightarrow \mathcal{O}_{Z} \rightarrow 0 \tag{10.8.1}
\end{equation*}
$$

where $Z$ is a 0 -dimensional scheme supported on $\operatorname{Sing} X$ together with the nonsingular points where $d f(x)=0$.

Let $P \in Z, P \in U_{\alpha}$. Assume that $f(P)=0 . f_{\alpha}=f \circ p_{\alpha}$ is a $G_{\alpha}$-invariant function on $X_{\alpha} . P$ has $\operatorname{deg} p_{\alpha} / r(P)$ inverse images in $X_{\alpha}$. For $0<|t| \ll 1$, $f_{\alpha}^{-1}(t)$ has the homotopy type of a wedge of $\mu_{P}$ circles in the neighbourhood of each point $Q \in p_{\alpha}^{-1}(P)$, hence its Euler number is $1-\mu_{P}$. Therefore if we fix a small neighbourhood of $P$, the intersection of $f^{-1}(t)$ with this neighbourhood
has orbifold Euler number $\frac{1-\mu_{P}}{r(P)}$ for $0<|t| \ll 1$. Thus

$$
e_{t o p}(X)=2(2-2 g)+\sum_{P \in Z}\left(\frac{\mu_{P}-1}{r(P)}+1\right)
$$

and

$$
\begin{equation*}
e_{o r b}(X)=2(2-2 g)+\sum_{P \in Z} \frac{\mu_{P}}{r(P)} \tag{10.8.2}
\end{equation*}
$$

$\mu_{P}$ can also be calculated as length $\left(\mathcal{O}_{X_{\alpha}, Q} /\left(\partial f_{\alpha} / \partial x, \partial f_{\alpha} / \partial y\right)\right)$ by Milnor's Theorem [Milnor68, §7]. Define a 0-dimensional subscheme $Z_{\alpha}$ of $X_{\alpha}$ with ideal $\left(\partial f_{\alpha} / \partial x, \partial f_{\alpha} / \partial y\right)$ ) at each $Q \in p_{\alpha}^{-1}(P)$. The $\mathcal{O}_{Z_{\alpha}}$ define the $Q$-sheaf structure of $\mathcal{O}_{Z}$.
$Z_{\alpha}$ is a local complete intersection as $X_{\alpha}$ is smooth, so we can define $\tilde{Z}$ by $\left.\tilde{Z}\right|_{\tilde{X}_{\alpha}}=q_{\alpha}^{*}\left(Z_{\alpha}\right)$, where $q_{\alpha}^{*}$ is the scheme theoretic inverse image. $\tilde{Z}$ is also a local complete intersection. We have the following lemma.
10.9 Lemma. If $\tilde{Z}$ is a zero dimensional local complete intersection subscheme of $\tilde{X}$, then $c_{2}\left(\mathcal{O}_{\tilde{Z}}\right)=-\operatorname{deg} \tilde{Z}$.

Proof. Both sides are clearly additive over subschemes with disjoint supports.
If $\tilde{Z}$ is a (reduced) smooth point $P$, then there exist smooth hyperplane sections $H_{1}, H_{2}$ such that $P \in H_{1} \cap H_{2}$, every point of intersection of $H_{1}$ and $H_{2}$ is smoothin $X$ and $H_{1}, H_{2}$ meet transversally there. Let $Y=H_{1} \cap H_{2}$. From the exact sequence

$$
0 \rightarrow \mathcal{O}\left(-H_{1}-H_{2}\right) \rightarrow \mathcal{O}\left(-H_{1}\right) \oplus \mathcal{O}\left(-H_{2}\right) \rightarrow \mathcal{I}_{Y} \rightarrow 0
$$

we can calculate $c_{2}\left(\mathcal{I}_{Y}\right)=H_{1} \cdot H_{2}$, hence $c_{2}\left(\mathcal{O}_{Y}\right)=-H_{1} \cdot H_{2} . c_{2}$ is invariant in an algebraic family, all points of $Y$ are algebraically equivalent on $H_{1}$, therefore $c_{2}\left(\mathcal{O}_{P}\right)=-1$.

In the general case, since $\tilde{Z}$ is a local complete intersection, there exists a sufficiently ample divisor $H$ such that $\mathcal{O}_{\tilde{Z}}(H)$ is generated by global sections and there exist $H_{1}, H_{2} \in|H|$ whose local equations generate the ideal of $\tilde{Z}$ in $\mathcal{O}_{\tilde{X}, P}$ for each point $P \in \operatorname{Supp} \tilde{Z}$, and all their other intersections are transversal and lie at smooth points of $\tilde{X}$. Let $Y$ be the scheme theoretic intersection of $H_{1}$ and $H_{2}$; then from the exact sequence we have $c_{2}\left(\mathcal{O}_{Y}\right)=-H_{1} \cdot H_{2}$ as before, and each point of $\operatorname{Supp} Y \backslash \operatorname{Supp} \tilde{Z}$ contributes $-1 . c_{2}\left(\mathcal{O}_{\tilde{Z}}\right)=-\operatorname{deg} \tilde{Z}$ in the general case.

In our case

$$
\operatorname{deg} \tilde{Z}=\sum_{P \in Z} \frac{\mu_{P} \operatorname{deg} q_{\alpha} \operatorname{deg} p_{\alpha}}{r(P)}=|G| \sum_{P \in Z} \frac{\mu_{P}}{r(P)}
$$

hence

$$
\begin{equation*}
\hat{c}_{2}\left(\mathcal{O}_{Z}\right)=\frac{1}{|G|} c_{2}\left(\mathcal{O}_{\tilde{Z}}\right)=-\frac{1}{|G|} \operatorname{deg} \tilde{Z}=-\sum_{P \in Z} \frac{\mu_{P}}{r(P)} \tag{10.8.3}
\end{equation*}
$$

From (10.8.1), (10.8.2) and (10.8.3) we obtain

$$
\begin{align*}
\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}\right) & =\hat{c}_{1}\left(f^{*} \Omega_{\mathbb{P}^{1}}^{1}\right) \hat{c}_{1}\left(\hat{\Omega}_{X / \mathbb{P}^{1}}\right)-\hat{c}_{2}\left(\mathcal{O}_{Z}\right) \\
& =2(2-2 g)+\sum_{P \in Z} \frac{\mu_{P}}{r(P)}=e_{o r b}(X) \tag{10.8.4}
\end{align*}
$$

Let $B_{1}, B_{2}, \ldots, B_{s}$ be the components of $B$. There exist $Q$-exact sequences

$$
\begin{align*}
0 & \rightarrow \mathcal{O}\left(-B_{i}\right) \rightarrow \mathcal{O}_{X} \rightarrow \mathcal{O}_{B_{i}} \rightarrow 0  \tag{10.8.5}\\
0 & \rightarrow \mathcal{O}_{B_{i}} \rightarrow \mathcal{O}_{B_{i}} \rightarrow \mathcal{O}_{W_{i}} \rightarrow 0
\end{align*}
$$

and

$$
\begin{equation*}
0 \rightarrow \hat{\Omega}_{X}^{1} \rightarrow \hat{\Omega}_{X}^{1}(\log B) \rightarrow \bigoplus_{i=1}^{s} \mathcal{O}_{B_{i}^{\nu}} \rightarrow 0 \tag{10.8.7}
\end{equation*}
$$

where $W_{i}$ is a 0-dimensional subscheme of $X$ supported at those points of $B_{i}$ which are either nodes of $B_{i}$ or singular points of $X$ of type (c) in Examples 10.3. ( $i i i$ ) on $B_{i}$. The $Q$-sheaf structure of $\mathcal{O}_{W_{i}}$ is given by $\mathcal{O}_{p_{\alpha}^{-1}\left(W_{i} \cap U_{\alpha}\right)}$ on $X_{\alpha}$, where $p_{\alpha}^{-1}$ denotes the set theoretic inverse image.

From (10.8.5) we see that $\hat{c}_{1}\left(\mathcal{O}_{B_{i}}\right)=B_{i}$ and $\hat{c}_{2}\left(\mathcal{O}_{B_{i}}\right)=B_{i}^{2}$, while from (10.8.6) and (10.9), $\hat{c}_{2}\left(\mathcal{O}_{B_{i}^{\nu}}\right)=\hat{c}_{2}\left(\mathcal{O}_{B_{i}}\right)+\hat{c}_{2}\left(\mathcal{O}_{W_{i}}\right)=B_{i}^{2}-\sum_{P \in W_{i}} \frac{1}{r(P)}$. Thus from (10.8.7) we obtain
(10.8.8) $\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}(\log B)\right)=\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}\right)+K_{X} \cdot B+\sum_{1 \leq i \leq j \leq s} B_{i} \cdot B_{j}-\sum_{i=1}^{s} \sum_{P \in W_{i}} \frac{1}{r(P)}$.

We have $Q$-exact sequences

$$
\left.0 \rightarrow \hat{\mathcal{N}}_{B_{i} / X}^{\vee} \rightarrow \hat{\Omega}_{X}^{1}\right|_{B_{i}} \rightarrow \hat{\Omega}_{B_{i}}^{1} \rightarrow 0
$$

where $\hat{\mathcal{N}}_{B_{i} / X}^{\vee}$ is the conormal $Q$-sheaf, obtained by taking the $G_{\alpha}$-invariants of $\mathcal{N}_{C_{\alpha} / X_{\alpha}}^{\vee}$, where $C_{\alpha}=p_{\alpha}^{-1}\left(\left.B_{i}\right|_{U_{\alpha}}\right)$. Now $\hat{c}_{1}\left(\left.\hat{\Omega}_{X}^{1}\right|_{B_{i}}\right)=K_{X} \cdot B_{i}$, while $\hat{c}_{1}\left(\hat{\mathcal{N}}_{B_{i} / X}^{\vee}\right)=-B_{i}^{2}+\sum_{P \in W_{i}} \frac{1}{r(P)}$, since each simple node of $C_{\alpha}$ contributes +1 on $X_{\alpha}$. Hence

$$
\begin{equation*}
\hat{c}_{1}\left(\hat{\Omega}_{B_{i}}^{1}\right)=K_{X} \cdot B_{i}+B_{i}^{2}-\sum_{P \in W_{i}} \frac{1}{r(P)} . \tag{10.8.9}
\end{equation*}
$$

10.10 Lemma. $\hat{c}_{1}\left(\hat{\Omega}_{B_{i}}^{1}\right)=-e_{\text {orb }}\left(B_{i}\right)$.

Proof. By an argument similar to the above, we can find a morphism $f$ : $B_{i} \rightarrow \mathbb{P}^{1}$ such that $f$ has only ordinary ramification points and these are all smooth points of $X$ and not nodes of $B_{i}$. Let $d$ be the degree of this map, $a$ the number of ramification points, $b$ the number of nodes of $B_{i}$. Then $e_{\text {top }}\left(B_{i}\right)=2 d-a-b$, and hence $e_{\text {orb }}\left(B_{i}\right)=2 d-a-b-\sum_{P \in B_{i} \text { กSing } X}\left(1-\frac{1}{r(P)}\right)$.

We determine $\hat{c}_{1}\left(\hat{\Omega}_{B_{i}}^{1}\right)$ from the $Q$-exact sequence

$$
0 \rightarrow f^{*} \Omega_{\mathbb{P}^{1}}^{1} \rightarrow \hat{\Omega}_{B_{i}}^{1} \rightarrow \hat{\Omega}_{B_{i} / \mathbb{P}^{1}}^{1} \rightarrow 0 ;
$$

the argument is similar to Hurwitz's formula.
Note first that $\hat{c}_{1}\left(f^{*} \Omega_{\mathbb{P}^{1}}^{1}\right)=-2 d$. Each ramification point of $f$ and each node of $B_{i}$ which is a smooth point of $X$ contributes 1 to $\hat{c}_{1}\left(\hat{\Omega}_{B_{i}}^{1} / \mathbb{P}^{1}\right)$. If a node $P \in B_{i}$ is a singular point of $X$, then it is type (c) in Examples 10.3. (iii). Let $P \in U_{\alpha}, f_{\alpha}=f \circ p_{\alpha}$. On $X_{\alpha}, C_{\alpha}=p_{\alpha}^{-1}\left(\left.B_{i}\right|_{U_{\alpha}}\right)$ has a simple node at each $Q \in p_{\alpha}^{-1}(P)$, and $Q$ is a ramification point of index $r(P)$ of $f_{\alpha}$ on each branch, therefore the contribution to $\hat{c}_{1}\left(\hat{\Omega}_{B_{i} / \mathbb{P}^{1}}^{1}\right)$ at $P$ is $\frac{2(r(P)-1)+1}{r(P)}=\left(2-\frac{1}{r(P)}\right)$. If $P \in B_{i}$ is a singular point of $X$ which is not a node of $B_{i}$ then it is of type (a) or (c) in Examples 10.3. (iii). Let $P \in U_{\alpha}$. If $P$ is of type (a), then on $X_{\alpha}$ each $Q \in p_{\alpha}^{-1}(P)$ is a ramification point of $f_{\alpha}$ of index $r(P)$, so the contribution to $\hat{c}_{1}\left(\hat{\Omega}_{B_{i} / \mathbb{P}^{1}}^{1}\right)$ is $1-\frac{1}{r(P)}$. If $P$ is of type $(c)$, then $r(P)=4 l, C_{\alpha}$ has a node at each $Q \in p_{\alpha}^{-1}(P)$, and $Q$ is a ramification point of index $2 l$ on both branches of $C_{\alpha}$, so the contribution to $\hat{c}_{1}\left(\hat{\Omega}_{B_{i} / \mathbb{P}^{1}}^{1}\right)$ at $P$ is $\frac{2(2 l-1)+1}{4 l}=\left(1-\frac{1}{r(P)}\right)$ in this case too.

Hence

$$
\begin{aligned}
& \hat{c}_{1}\left(\hat{\Omega}_{B_{i}}^{1}\right)=\hat{c}_{1}\left(f^{*} \Omega_{\mathbb{P}^{1}}\right)+\hat{c}_{1}\left(\hat{\Omega}_{B_{i} / \mathbb{P}^{1}}^{1}\right) \\
& =-2 d+a+b+\sum_{P \in B_{i} \cap \operatorname{Sing} X}\left(1-\frac{1}{r(P)}\right)=-e_{\text {orb } b}\left(B_{i}\right) .
\end{aligned}
$$

For $i \neq j, B_{i} \cdot B_{j}=\sum_{P \in B_{i} \cap B_{j}} \frac{1}{r(P)}=\sum_{P \in B_{i} \cap B_{j}} e_{\text {orb }}(P)$. Hence by (10.8.9) and (10.10),

$$
\begin{aligned}
e_{o r b}(B) & =\sum_{i=1}^{s} e_{o r b}\left(B_{i}\right)-\sum_{1 \leq i \leq j \leq s} \sum_{P \in B_{i} \cap B_{j}} e_{o r b}(P) \\
& =-K_{X} \cdot B-\sum_{1 \leq i \leq j \leq s} B_{i} \cdot B_{j}+\sum_{i=1}^{s} \sum_{P \in W_{i}} \frac{1}{r(P)} .
\end{aligned}
$$

Combining this with (10.8.4), we obtain

$$
\hat{c}_{2}\left(\hat{\Omega}_{X}^{1}(\log B)\right)=e_{\text {orb }}(X)-e_{\text {orb }}(B)=e_{\text {orb }}(X \backslash B) .
$$

Next we generalize some results from sheaves on smooth varieties to $Q$ sheaves on $Q$-varieties.
10.11 Lemma. Let $\mathcal{F}$ be a $Q$-vector bundle of rank $r$ on a normal projective surface $X$ with only quotient singularities. If

$$
(r-1)\left(\hat{c}_{1}(\mathcal{F})\right)^{2}-2 r \hat{c}_{2}(\mathcal{F})>0,
$$

then $\mathcal{F}$ is $H$-unstable for any numerically nontrivial nef divisor $H$ on $X$, i.e., there exists a saturated $Q$-subsheaf $\mathcal{E}$ of $\mathcal{F}$ such that

$$
\begin{equation*}
\frac{\hat{c}_{1}(\mathcal{E}) \cdot H}{\operatorname{rk} \mathcal{E}}>\frac{\hat{c}_{1}(\mathcal{F}) \cdot H}{r} \tag{10.11.1}
\end{equation*}
$$

Proof. Let $\pi: X^{*} \rightarrow \tilde{X}$ be the minimal resolution of the singularities of $\tilde{X}$. Let $\tilde{H}=p^{*} H, H^{*}=\pi^{*} \tilde{H}, \mathcal{F}^{*}=\pi^{*} \tilde{\mathcal{F}}$. Then

$$
(r-1)\left(c_{1}\left(\mathcal{F}^{*}\right)\right)^{2}-2 r c_{2}\left(\mathcal{F}^{*}\right)=(r-1)\left(c_{1}(\tilde{\mathcal{F}})\right)^{2}-2 r c_{2}(\tilde{\mathcal{F}})>0,
$$

so by [Bogomolov79, Theorem 3], there exists a saturated subsheaf $\mathcal{E}^{*}$ of $\mathcal{F}^{*}$ such that

$$
\left(\frac{c_{1}\left(\mathcal{E}^{*}\right)}{\operatorname{rk} \mathcal{E}}-\frac{c_{1}\left(\mathcal{F}^{*}\right)}{r}\right)^{2}>0 \quad \text { and } \quad\left(\frac{c_{1}\left(\mathcal{E}^{*}\right)}{\operatorname{rk} \mathcal{E}}-\frac{c_{1}\left(\mathcal{F}^{*}\right)}{r}\right) \cdot D>0
$$

for any ample divisor $D$ on $X^{*}$. Therefore also

$$
\left(\frac{c_{1}\left(\mathcal{E}^{*}\right)}{\operatorname{rk} \mathcal{E}}-\frac{c_{1}\left(\mathcal{F}^{*}\right)}{r}\right) \cdot H^{*}>0
$$

since $H^{*}$ is nef and not numerically trivial.
Then $\pi_{*} \mathcal{E}^{*} \hookrightarrow \pi_{*} \mathcal{F}^{*}=\mathcal{F}$ and $c_{1}\left(\pi_{*} \mathcal{E}^{*}\right) \cdot \tilde{H}=c_{1}(\tilde{\mathcal{E}}) \cdot \tilde{H}$, since $\tilde{H}$ is ample, so some multiple of it can be moved away from the singular locus of $\tilde{X}$, and the sheaves $\pi_{*} \mathcal{E}^{*}, \tilde{\mathcal{E}}$ agree on the smooth locus of $\tilde{X}$. Having obtained the instability of $\tilde{\mathcal{F}}$ on $\tilde{X}$, we can now choose a $G$-invariant destabilizing subsheaf, namely the first step $\mathcal{E}_{1}$ in the Harder-Narasimhan filtration of $\mathcal{F}$ for $\tilde{H}$ [Miyaoka87b, Theorem 2.1], which is unique, therefore $G$-invariant. Taking $G$-invariants, we obtain the required destabilizing $Q$-subsheaf $\mathcal{E}=\tilde{\mathcal{E}}_{1}^{G}$ of $\mathcal{F}$, then (10.11.1) follows from

$$
\frac{c_{1}\left(\mathcal{E}_{1}\right) \cdot \tilde{H}}{\operatorname{rk} \mathcal{E}_{1}}>\frac{c_{1}(\tilde{\mathcal{F}}) \cdot \tilde{H}}{r} .
$$

10.12 Proposition. Let $\mathcal{E}$ be a $Q$-locally free sheaf on a normal projective surface $X$ with only quotient singularities such that $\hat{c}_{1}(\mathcal{E})$ is nef and $\mathcal{E}$ is generically semipositive, i.e., for any nef divisor $D$ on $X$ and for any torsion free quotient $Q$-sheaf $\mathcal{F}, \hat{c}_{1}(\mathcal{F}) \cdot D \geq 0$. Then $\hat{c}_{2}(\mathcal{E}) \geq 0$.

Proof. Let $H$ be an ample divisor on $X, t$ a positive rational number, then $H_{t}=\hat{c}_{1}(\mathcal{E})+t H$ is an ample $\mathbb{Q}$-divisor. Let $0=\mathcal{E}_{0} \subset \mathcal{E}_{1} \subset \mathcal{E}_{1} \subset \ldots \subset$ $\mathcal{E}_{s}=\mathcal{E}$ be the Harder-Narasimhan filtration for $\mathcal{E}$ with respect to $H_{t}$, which is obtained by taking the $G$-invariants of the Harder-Narasimhan filtration for $\tilde{\mathcal{E}}$ with respect to $p^{*} H_{t}$. Let $\mathcal{G}_{i}=\left(\mathcal{E}_{i} / \mathcal{E}_{i-1}\right)^{\vee v}, r_{i}=\operatorname{rk} \mathcal{G}_{i}$. $\mathcal{E}_{i} / \mathcal{E}_{i-1} \subset$ $\mathcal{G}_{i}$ with skyscraper cokernel, therefore $\hat{c}_{2}\left(\mathcal{E}_{i} / \mathcal{E}_{i-1}\right) \geq \hat{c}_{2}\left(\mathcal{G}_{i}\right)$ by (10.9), while $\hat{c}_{1}\left(\mathcal{E}_{i} / \mathcal{E}_{i-1}\right)=\hat{c}_{1}\left(\mathcal{G}_{i}\right)$, since they agree in codimension 1. $\hat{c}(\mathcal{E})=\prod_{i=1}^{s} \hat{c}\left(\mathcal{E}_{i} / \mathcal{E}_{i-1}\right)$, where $\hat{c}$ is the total Chern class, therefore

$$
\begin{aligned}
\hat{c}_{2}(\mathcal{E}) & \geq \prod_{1 \leq i<j \leq s} \hat{c}_{1}\left(\mathcal{G}_{i}\right) \hat{c}_{1}\left(\mathcal{G}_{j}\right)+\sum_{i=1}^{s} \hat{c}_{2}\left(\mathcal{G}_{i}\right) \\
& =\frac{1}{2}(\hat{c}(\mathcal{E}))^{2}+\sum_{i=1}^{s} \hat{c}_{2}\left(\mathcal{G}_{i}\right)-\frac{1}{2} \sum_{i=1}^{s}\left(\hat{c}_{1}\left(\mathcal{G}_{i}\right)\right)^{2} \\
& \geq \frac{1}{2}\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-\sum_{i=1}^{s} \frac{1}{2 r_{i}}\left(\hat{c}_{1}\left(\mathcal{G}_{i}\right)\right)^{2}
\end{aligned}
$$

where in the last step we used the semistability of the $\mathcal{G}_{i}$ and Lemma 10.11 .
Let $\alpha_{i}=\frac{\hat{c}_{1}\left(\mathcal{G}_{i}\right) \cdot H_{t}}{r_{i} H_{t}^{2}}$; then $\alpha_{1}>\alpha_{2}>\ldots \alpha_{s} \geq 0$ by definition of the Harder-Narasimhan filtration and the generic semipositivity of $\mathcal{E}$. By the

Hodge Index Theorem, $\left(\hat{c}_{1}\left(\mathcal{G}_{i}\right)\right)^{2} \leq r_{i}^{2} \alpha_{i}^{2} H_{t}^{2}$. Hence

$$
\begin{aligned}
\hat{c}_{2}(\mathcal{E}) & \geq \frac{1}{2}\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-\sum_{i=1}^{s} \frac{1}{2 r_{i}}\left(\hat{c}_{1}\left(\mathcal{G}_{i}\right)\right)^{2} \\
& \geq \frac{1}{2}\left(\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-\sum_{i=1}^{s} r_{i} \alpha_{i}^{2} H_{t}^{2}\right) \\
& \geq \frac{1}{2}\left(\left(\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-H_{t}^{2}\right)+\left(1-\sum_{i=1}^{s} r_{i} \alpha_{i}^{2}\right) H_{t}^{2}\right) \\
& \geq \frac{1}{2}\left(\left(\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-H_{t}^{2}\right)+\left(1-\alpha_{1} \sum_{i=1}^{s} r_{i} \alpha_{i}\right) H_{t}^{2}\right) \\
& =\frac{1}{2}\left(\left(\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-H_{t}^{2}\right)+\left(1-\alpha_{1}\right) H_{t}^{2}\right) .
\end{aligned}
$$

Now $\alpha_{1}=\frac{\hat{c}_{1}\left(\mathcal{G}_{1}\right) \cdot H_{t}}{r_{1} H_{t}^{2}} \leq \frac{\hat{c}_{1}(\mathcal{E}) \cdot H_{t}}{r_{1} H_{t}^{2}}<1$, whereas $\left(\hat{c}_{1}(\mathcal{E})\right)^{2}-H_{t}^{2} \rightarrow 0$ as $t \rightarrow 0$, so that $\hat{c}_{2}(\mathcal{E}) \geq 0$.
10.13 Theorem. Let $X$ be a normal projective threefold, $B$ a reduced Weil divisor on $X$, such that $(X, B)$ is $\log$ canonical, $(X, \emptyset)$ is log terminal, $K_{X}+B$ is nef and $X$ is not uniruled. Let $S$ be a general hyperplane section of $X$; then $\hat{c}_{2}\left(\left.\hat{\Omega}_{X}^{1}(\log B)\right|_{S}\right) \geq 0$.

Proof. $X$ has quotient singularities in codimension 2 , so $\hat{\Omega}_{X}^{1}(\log B)$ can be defined as a $Q$-vector bundle except at finitely many points. $S$ has only quotient singularities, $\left(S,\left.B\right|_{S}\right)$ is $\log$ canonical, so $\left.\hat{\Omega}_{X}^{1}(\log B)\right|_{S}$ is a $Q$-vector bundle. $\left.\hat{\Omega}_{X}^{1}\right|_{S}$ is generically semipositive by $(9.0 .1)$, therefore so is $\left.\hat{\Omega}_{X}^{1}(\log B)\right|_{S}$. $\hat{c}_{1}\left(\left.\hat{\Omega}_{X}^{1}(\log B)\right|_{S}\right)=\left.\left(K_{X}+B\right)\right|_{S}$ is nef by assumption, therefore we can apply (10.12) to deduce the result.

We prove a generalization of the Bogomolov-Miyaoka-Yau inequality $c_{1}^{2} \leq$ $3 c_{2}$. This inequality was proved for smooth surfaces of general type in [Miyaoka77, Theorem 4] and for smooth surfaces with $c_{1}$ negative in [Yau77, Theorem 4.]. It was generalised to $c_{1}^{2}\left(\Omega_{X}^{1}(\log B)\right) \leq 3 c_{2}\left(\Omega_{X}^{1}(\log B)\right)$ in [Sakai80, Theorem 7.6] for the case when $X$ is a smooth surface and $B \subset X$ is a semistable curve, which implies that $K_{X}+B$ is nef and $(X, B)$ is $\log$ canonical. [Miyaoka84, Theorem 1.1] deals with the log case on surfaces with quotient singularities when the curve $B$ does not pass through the singular points of the surface. A version of this inequality for $\log$ canonical surfaces with fractional boundary divisor with $K_{X}+B$ ample is proved in [KNS89, Theorem 12]. We
give a new method of proof for the case when $X$ has only quotient singularities, $(X, B)$ is $\log$ canonical, $K_{X}+B$ is nef. Our result is more general than [Miyaoka84] in that we also allow the curve $B$ to pass through the singular points.
10.14 Theorem. Let $X$ be a normal projective surface with only quotient singularities, $B \subset X$ a curve such that $(X, B)$ is $\log$ canonical and $K_{X}+B$ is nef. Then

$$
\hat{c}_{1}^{2}\left(\hat{\Omega}_{X}^{1}(\log B)\right) \leq 3 \hat{c}_{2}\left(\hat{\Omega}_{X}^{1}(\log B)\right)
$$

Proof. We prove this theorem by reducing it to the smooth case. Let $\mathcal{F}=$ $\hat{\Omega}_{X}^{1}(\log B)$. Let $\pi: X^{*} \rightarrow \tilde{X}$ be an embedded resolution of $\left(\tilde{X}, p^{-1}(B)_{\text {red }}\right)$, let $B^{*}=\left((\pi \circ p)^{-1}(B)\right)_{r e d}, \mathcal{F}^{*}=\pi^{*} \tilde{\mathcal{F}}$. Since $c_{i}\left(\mathcal{F}^{*}\right)=\pi^{*} c_{i}(\tilde{\mathcal{F}})$, it is sufficient to prove that $c_{1}^{2}\left(\mathcal{F}^{*}\right) \leq 3 c_{2}\left(\mathcal{F}^{*}\right)$.
$\mathcal{F}$ is locally free of rank 2 , therefore so is $\mathcal{F}^{*} .\left.\mathcal{F}\right|_{\tilde{X}_{\alpha}}=q_{\alpha}^{*} \Omega_{X_{\alpha}}^{1}\left(\log C_{\alpha}\right)$, where $C_{\alpha}=p_{\alpha}^{-1}\left(\left.B\right|_{U_{\alpha}}\right)$, hence $\left.\mathcal{F}^{*}\right|_{\pi^{-1} \tilde{X}_{\alpha}}=\left.\pi^{*} q_{\alpha}^{*} \Omega_{X_{\alpha}}^{1}\left(\log C_{\alpha}\right) \subset \Omega_{X^{*}}^{1}\left(\log B^{*}\right)\right|_{\pi^{-1} X_{\alpha}}$, therefore $\mathcal{F}^{*} \subset \Omega_{X^{*}}^{1}\left(\log B^{*}\right)$. If $B=\emptyset, \mathcal{F}^{*} \subset \Omega_{X^{*}}^{1}$.

If $\omega \in H^{0}\left(X^{*}, \Omega_{X^{*}}^{1}\left(\log B^{*}\right)\right)$, then $\omega$ is $d$-closed by [Deligne71]. (See also [Griffiths-Schmid73, 6.5] for a simpler proof.) Thus we can prove that if $\mathcal{L} \hookrightarrow$ $\Omega_{X^{*}}^{1}\left(\log B^{*}\right)$ is an invertible sheaf, then $h^{0}\left(X, \mathcal{L}^{\otimes n}\right) \leq c n$ for some constant $c$ [Sakai80, Lemma 7.5]. Using this, and the fact that $c_{1}(\mathcal{F})=\pi^{*} p^{*}\left(K_{X}+B\right)$ is nef, we can follow Miyaoka's original proof for the non-log case [Miyaoka77, Theorem 4] to obtain $c_{1}^{2}\left(\mathcal{F}^{*}\right) \leq 3 c_{2}\left(\mathcal{F}^{*}\right)$.
10.15 Corollary. [Miyaoka84, Proposition 2.1.1] Let $\hat{X}$ be a minimal surface of nonnegative Kodaira dimension. Then the number of disjoint smooth rational curves on $\hat{X}$ is at most $\frac{2}{9}\left(3 c_{2}(\hat{X})-c_{1}^{2}(\hat{X})\right)$.
Proof. $K_{\hat{X}}$ is nef as $\hat{X}$ is minimal, so $C^{2} \leq-2$ for any smooth rational curve on $\hat{X}$ by the adjunction formula. Let $X$ be the surface obtained by contracting some disjoint smooth rational curves to singular points. Contracting a smooth rational curve with selfintersection $-n$ increases $\hat{c}_{1}^{2}$ by $\frac{(n-2)^{2}}{n}$, decreases $\hat{c}_{2}$ by $2-\frac{1}{n}$, so $3 \hat{c}_{2}-\hat{c}_{1}^{2}$ decreases by at least $\frac{9}{2} . K_{X}$ is still nef, so by the previous theorem $3 \hat{c}_{2}(X)-\hat{c}_{1}^{2}(X) \geq 0$, which gives the bound on the number of contracted curves.

# 11. LOG ABUNDANCE FOR SURFACES 

Lung-Ying Fong and James MCKernan

### 11.1 Introduction

Chapters 11-14 present Kawamata and Miyaoka's proof of the abundance theorem for threefolds.
11.1.1 Abundance Theorem. A three dimensional minimal model $X$ has a free pluricanonical system, that is, there exists a positive integer $m$ such that $\left|m K_{X}\right|$ has no base points.
(1.22-29) contains a general introduction to Abundance, and to the contents of Chapters 11-14. The division of labour indicated by the authors listed for each chapter is somewhat arbitrary; every author has made a significant contribution to each chapter. We would like to thank Kawamata for answering questions regarding his original version of [Kawamata91b]. We would also like to thank Shepherd-Barron, and Corti among others for helpful discussions and comments.

The purpose of this chapter is to gather together and prove some facts concerning log abundance for surfaces. These facts will be needed in Chapters $12-14$ to prove the abundance conjecture for threefolds. We collect together some standard definitions and notation.

### 11.1.2 Notation

$\kappa(X, D)$ denotes the Iitaka dimension of the pair $(X, D)$. By definition $\kappa(X, D)=-\infty$ iff $h^{0}\left(\mathcal{O}_{X}(n D)\right)=0$ for every $n>0$, and $\kappa(X, D)=k>-\infty$ iff

$$
0<\lim \sup \frac{h^{0}\left(\mathcal{O}_{X}(n D)\right)}{n^{k}}<\infty
$$

One can see that $\kappa(X, D) \in\{-\infty, 0,1, \ldots, \operatorname{dim} X\}$.
$\kappa(X)=\kappa\left(X, K_{X}\right)$ is the Kodaira dimension of X .
In case the divisors are nef, we can define the numerical counterparts (cf. (1.28)):

$$
\begin{aligned}
& \nu(X, D)=\max \left\{n \in \mathbb{N} \cup 0 \mid\left(D^{n}\right) \text { not numerically } 0\right\} \\
& \nu(X)=\nu\left(X, K_{X}\right) .
\end{aligned}
$$

S. M. F.

The log abundance theorem for a normal surface $X$ asserts the following:
11.1.3 Theorem. Let $(X, \Delta)$ be a normal surface with boundary $\Delta$ (see (2.2.4) for a definition). If $K_{X}+\Delta$ is $\mathbb{Q}$-Cartier, nef and log canonical then $\left|m\left(K_{X}+\Delta\right)\right|$ is basepoint free for some $m$ (and in particular $\nu\left(X, K_{X}+\Delta\right)=$ $\left.\kappa\left(X, K_{X}+\Delta\right)\right)$.

We need (11.1.3) in the cases $\nu\left(K_{X}+\Delta\right)=0$ and 1 , and content ourselves with proving these cases only. Readers interested in seeing the other case should consult [Fujita84]. The proof presented here is different from that in [Fujita84] at various points, and is adapted from Miyaoka's proof of the abundance theorem in the threefold case, as will be evident to the readers. Following Miyaoka's idea, we extend (11.1.3) to the semi log canonical case in Chapter 12.

The idea of the proof is as follows: we first show that the linear system $\left|m\left(K_{X}+\Delta\right)\right|$ contains a divisor $D(11.2 .1)$. Then we replace $D$ with $B=D_{\text {red }}$, and apply the log minimal model program to $(X, \Delta+B)$, so that $K_{X}+\Delta+B$ becomes nef (11.3.2). Then we use a further series of log extremal contractions to make each connected component of $B$ irreducible (11.3.4). Next we make a cyclic cover of a neighborhood of a connected component of $B$, to improve how it sits inside $X$ (11.3.6). Finally using some simple cohomological arguments, one can show that this component moves to any infinitesimal order (11.3.7).

### 11.2 EXISTENCE OF AN EFFECTIVE MEMBER

We start with the following lemma.
11.2.1 Lemma. Let $(X, \Delta)$ be a smooth surface with boundary $\Delta$. If $K_{X}+\Delta$ is nef then $\kappa\left(X, K_{X}+\Delta\right) \geq 0$. In other words, there exists a member $D \in$ $\left|m\left(K_{X}+\Delta\right)\right|$ for some $m>0$.
11.2.2 Remark An analog of this result for threefolds is proved in Chapter 9.

Proof. (cf. [Fujita84, §2]) If $\kappa\left(X, K_{X}\right) \geq 0$ then the conclusion is clear. Thus we may assume that $X$ is ruled. There are two cases to consider, $X$ is rational or irrational.

First consider the case when $X$ is rational. Let $G=K_{X}+\Delta . G$ is nef by assumption. Since $X$ is rational, $h^{1}\left(\mathcal{O}_{X}\right)=0$. Therefore if $G$ is numerically trivial, then $m G \sim 0$ for some $m$. Otherwise $h^{2}(m G)=h^{0}(-(m-1) G-\Delta)=0$ for $m \geq 2$ and sufficiently divisible. Now $\chi\left(\mathcal{O}_{X}\right)=1$, and so Riemann-Roch reads

$$
h^{0}(X, m G)=h^{1}(X, m G)+\frac{1}{2} m G \cdot\left(m G-K_{X}\right)+1
$$

Note that $m G-K_{X}=(m-1) G+\Delta$ and $\Delta$ is a sum of effective divisors. Since $G$ is nef, we have $G \cdot\left(m G-K_{X}\right) \geq 0$ and therefore $h^{0}(X, m G)>0$. This proves the lemma for rational surfaces.

Next consider the case when $X$ is irrational. We write $\Delta=\Delta_{1}+\Delta_{2}$, where $\Delta_{1}$ and $\Delta_{2}$ are boundaries, in such a way that $\Delta_{1}$ has no vertical components, and furthermore $\left(K_{X}+\Delta_{1}\right) \cdot F=0$. (11.2.1) follows if we show that $\left|m\left(K_{X}+\Delta_{1}\right)\right| \neq \emptyset$. Thus we may as well assume that $\left(K_{X}+\Delta\right) \cdot F=0$ to start with, i.e., we prove the stronger statement:
11.2.3 lemma. Let $(X, \Delta)$ be an irrational ruled surface with boundary $\Delta$. Ssuppose that $\Delta$ has no vertical components and $\left(K_{X}+\Delta\right) \cdot F=0$. Then $\kappa\left(X, K_{X}+\Delta\right) \geq 0$.

The proof is by induction on the Picard number $\rho(X)$. Consider the case when $X$ is a $\mathbb{P}^{1}$-bundle.
$\rho(X)=2$, and the cone $\overline{\mathrm{NE}}(X)$ has two edges. One is the class generated by $F$, a fibre of the ruling $\pi: X \rightarrow C$ with $C$ of genus $g>0$. Suppose that the other edge is generated by $H$. Since $F^{2}=0$ and $H^{2} \leq 0$ (see [CKM88, 4.4]), we must have $H \cdot F>0$. We normalize $H$ by taking $H \cdot F=1$.

Let $\Delta=\sum k_{i} \Delta_{i}$, where the $\Delta_{i}$ are the prime components of $\Delta$. We have $\Delta_{i} \equiv a_{i} H+F_{i}$, where $a_{i} \in \mathbb{Z}$ and $F_{i}=\pi^{*}\left(D_{i}\right)$ for some divisor $D_{i}$ on $C$. Let $b_{i}=\operatorname{deg}\left(D_{i}\right)$. Since $\Delta_{i}$ is not a vertical component, $a_{i}>0$. We also know that $K_{X} \equiv-2 H+F_{0}$, with $F_{0}=\pi^{*}\left(D_{0}\right)$, deg $\left(D_{0}\right)=H^{2}+2 g-2$. Hence

$$
\begin{equation*}
K_{X}+\Delta \equiv\left(-2+\sum k_{i} a_{i}\right) H+\sum F_{i} \tag{11.2.3.1}
\end{equation*}
$$

By assumption $\left(K_{X}+\Delta\right) \cdot F=0$, and so $\sum k_{i} a_{i}=2$. Now $\sum F_{i}=\pi^{*}\left(\sum D_{i}\right)$ and $\operatorname{deg}\left(\sum D_{i}\right)=H^{2}+2 g-2+\sum k_{i} b_{i}$.

Look at $H \cdot \Delta_{i}$. If $H \cdot \Delta_{i} \geq 0$, then $b_{i} \geq-a_{i} H^{2} \geq 0$. Otherwise $H \cdot \Delta_{i}<0$, but since $H$ is an edge of $\overline{\mathrm{NE}}(X)$, this implies that $\Delta_{i}^{2}<0$. Hence $\Delta_{i}$ is a section of the ruling of $X$ with negative selfintersection. Moreover according to [CKM88, 4.5], the class of $\Delta_{i}$ is an edge, and so $\Delta_{i}$ is proportional to $H$. By the normalization $H \cdot F=1, H$ is the class generated by $\Delta_{i}$, and we can replace numerical equivalence in (11.2.3.1) by linear equivalence. In particular, $a_{i}=1$ and $D_{i}=0$.

Now we have the following two cases:
Case (i). If $H \cdot \Delta_{i} \geq 0$ for all $i$, then $\sum k_{i} b_{i} \geq-\left(\sum a_{i} k_{i}\right) H^{2}=-2 H^{2}$, and so $H^{2}+2 g-2+\sum k_{i} b_{i} \geq-H^{2}+2 g-2$.

Case (ii). The other possibility is that $H \cdot \Delta_{1}<0$, in which case $H$ is generated by $\Delta_{1}$ and $H \cdot \Delta_{i} \geq 0$ for all $i \neq 1$. Then $\sum k_{i} b_{i} \geq-2 H^{2}+k_{1} H^{2}$, and so $H^{2}+2 g-2+\sum k_{i} b_{i} \geq-\left(1-k_{1}\right) H^{2}+2 g-2$. Note that since $\Delta$ is a boundary, $k_{1} \leq 1$.

When $g>1$, in either case, $\operatorname{deg}\left(\sum D_{i}\right)>0$, which implies (11.2.3).
We are left with the case $g=1$ and $\operatorname{deg}\left(\sum D_{i}\right)=0$. This implies, in case (ii), that $\Delta_{1}=H$ is an elliptic curve, $H^{2}<0, k_{1}=1$ and $\Delta_{i} \cdot H=0$ for $i \geq 2$. Thus $H$ is disjoint from $\Delta_{i}$, for $i \geq 2$ and so $\left.\left(K_{X}+\Delta\right)\right|_{H}=K_{H} \sim 0$. Therefore $K_{X}+\Delta \sim 0$.

In case (i), this implies $H^{2}=0$ and $b_{i}=0$ for all $i$. Then $H$ is the class of a section with selfintersection 0 and we denote the section by $H$. We also replace the numerical equivalence by linear equivalence. Then $K_{X} \sim-2 H$, and $\Delta_{i} \cdot \Delta_{j}=0$ for any $i$ and $j$. Applying adjunction to $\Delta_{i}$, we see that each $\Delta_{i}$ is a smooth elliptic curve. Now $\pi$ restricts to an étale map from $\Delta_{i}$ to $C$ of degree $a_{i}$.

As the $\Delta_{i}$ are disjoint, we can find an étale cover $p: \tilde{C} \rightarrow C$, so that on the fibre product $\tilde{\pi}: \tilde{X} \rightarrow \tilde{C}$, the pull back by $\tilde{p}$ of $\Delta$ is a disjoint union of $n=\sum a_{i}$ sections of $\tilde{\pi}$. Since $\tilde{p}$ is étale, $\tilde{p}^{*}\left(K_{X}\right)=K_{\tilde{X}}$. Now if $n \geq 3$, then $\tilde{X}$ is actually $\tilde{C} \times \mathbb{P}^{1}$, and $\tilde{p}^{*}\left(K_{X}+\Delta\right)$ is trivial. If $n<3$, as $\sum k_{i} a_{i}=2, n$ must be 2 , and on $\tilde{X}, \tilde{p}^{*}(\Delta)=\tilde{\Delta}_{1}+\tilde{\Delta}_{2}$. It is then clear that both $K_{\tilde{X}}$ and $\mathcal{O}_{\tilde{X}}\left(-\tilde{\Delta}_{1}-\tilde{\Delta}_{2}\right)$ are the relative dualizing sheaf for $\tilde{\pi}$. Thus $\tilde{p}^{*}\left(K_{X}+\Delta\right)$ is still trivial. But $\tilde{p}^{*}\left(K_{X}+\Delta\right)=\tilde{\pi}^{*} p^{*}\left(\sum D_{i}\right)$. Therefore $p^{*}\left(\sum D_{i}\right) \sim 0$, and $r\left(\sum D_{i}\right)=p_{*} p^{*}\left(\sum D_{i}\right) \sim 0$, where $r$ is the degree of $p$, that is $\sum D_{i}$ is a torsion class on $C$. This finishes the proof of (11.2.3) when $X$ is a $\mathbb{P}^{1}$-bundle.

Now suppose that $\pi$ has a singular fibre and $E$ is a component of the singular fibre. If $E$ is not a -1-curve, then $E \cdot K_{X} \geq 0$. Since $\Delta$ contains no vertical component, $\left(K_{X}+\Delta\right) \cdot E \geq 0$. By assumption, $\left(K_{X}+\Delta\right) \cdot F=0$, hence $\left(K_{X}+\Delta\right) \cdot E \leq 0$ for some exceptional curve $E$ of the singular fibre. We may blow down $E$ to get $p: X \rightarrow X^{\prime}$. Set $\Delta^{\prime}=p_{*} \Delta$. We have $K_{X}+\Delta=$ $p^{*}\left(K_{X^{\prime}}+\Delta^{\prime}\right)+\alpha E$, with $\alpha=-E \cdot\left(K_{X}+\Delta\right) \geq 0$. Clearly $K_{X^{\prime}}+\Delta^{\prime}$ satisfies the inductive assumption, hence $\kappa\left(X^{\prime}, K_{X^{\prime}}+\Delta^{\prime}\right) \geq 0$. It follows at once that $\kappa\left(X, K_{X}+\Delta\right) \geq 0$.

The $\log$ abundance theorem for the case $\nu\left(X, K_{X}+\Delta\right)=0$ is a direct consequence of (11.2.1).
11.2.4 Lemma. Let $X$ be a proper surface and assume that $(X, \Delta)$ is $\log$ canonical. If $K_{X}+\Delta$ is nef then $\kappa\left(X, K_{X}+\Delta\right) \geq 0$.
Proof. We want to find a member in $\left|m\left(K_{X}+\Delta\right)\right|$. For this let $\phi: X^{\prime} \rightarrow X$ be the minimal resolution, and write $K_{X^{\prime}}+\Delta_{X^{\prime}}=\phi^{*}\left(K_{X}+\Delta\right)$. Since $K_{X}+\Delta$ is $\log$ canonical and $\phi$ is minimal, $\Delta_{X^{\prime}}$ is a boundary. As $K_{X^{\prime}}+\Delta_{X^{\prime}}$ is nef, (11.2.1) implies that $\left|m\left(K_{X^{\prime}}+\Delta_{X^{\prime}}\right)\right| \neq \emptyset$. But $\mathrm{H}^{0}\left(m\left(K_{X^{\prime}}+\Delta_{X^{\prime}}\right)\right)=$ $\mathrm{H}^{0}\left(m\left(K_{X}+\Delta\right)\right.$, and so we can find $D \in\left|m\left(K_{X}+\Delta\right)\right|$.

$$
\text { 11.3 The Case } \nu\left(K_{X}+\Delta\right)=1
$$

This section is devoted to a proof of the following result.
11.3.1 Theorem. Let $(X, \Delta)$ be a normal surface with boundary $\Delta$. If $K_{X}+$ $\Delta$ is nef, $\mathbb{Q}$-Cartier, log canonical and $\nu\left(X, K_{X}+\Delta\right)=1$, then $\left|m\left(K_{X}+\Delta\right)\right|$ is free for some $m$.

We first observe that to prove (11.3.1), it is enough to show that $\kappa\left(X, K_{X}+\right.$ $\Delta)=1$. In fact suppose $M+B \in\left|m\left(K_{X}+\Delta\right)\right|$, where $M$ moves in a pencil, and $B$ is the fixed part. Now $M \cdot B \geq 0$, as $|M|$ has no one dimensional base locus, and since $(M+B)^{2}=0$, this implies $M(M+B)=M^{2}=0$. Thus $|M|$ is free, and so it defines a map of $S$ to a smooth curve $C$. As $M \cdot B=0$ and the numerical class of $M$ is equivalent to a multiple of a fibre, the divisor $B$ is linearly equivalent to the pullback of a divisor from $C$. But then some multiple of $B$ is base point free.

Here is the first step of (11.3.1).
11.3.2 Lemma. There exists a surface $\hat{X}$ birational to $X$, and divisors $\hat{\Delta}$, $\hat{B}$ and $\hat{D}$ such that:
(1) $(\hat{X}, \hat{\Delta}+\hat{B})$ is $\mathbb{Q}$-factorial and $\log$ canonical and $\hat{D} \in\left|m\left(K_{\hat{X}}+\hat{\Delta}+\hat{B}\right)\right|$. Moreover $\hat{B}=\hat{D}_{\text {red }}$.
(2) $K_{\hat{X}}+\hat{\Delta}+\hat{B}$ is nef.
(3) $\nu\left(X, K_{X}+\Delta\right)=\nu\left(X, K_{\hat{X}}+\hat{\Delta}+\hat{B}\right)$ and $\kappa\left(X, K_{X}+\Delta\right)=\kappa\left(\hat{X}, K_{\hat{X}}+\right.$ $\hat{\Delta}+\hat{B})$.

Proof. By (11.2.4), we may find $D \in\left|m\left(K_{X}+\Delta\right)\right|$. Pick a minimal good resolution $\mu: X_{0} \longrightarrow X$ of the pair $(X, D+\Delta)$, and write $K_{X_{0}}+\tilde{\Delta}=$ $\mu^{*}\left(K_{X}+\Delta\right)$. As $(X, \Delta)$ is $\log$ canonical, $\tilde{\Delta}$ is effective. Set $B_{0}=\left(\mu^{*} D\right)_{\text {red }}$ and replace $\tilde{\Delta}$ with $\Delta_{0}$, where we only include those components of $\tilde{\Delta}$ which are not components of $B_{0}$. With this choice of $\Delta_{0}, \Delta_{0}+B_{0}$ is a boundary, and there is a divisor $D_{0} \in\left|m\left(K_{X_{0}}+\Delta_{0}+B_{0}\right)\right|$.

We now apply the $\log$ minimal model program to $\left(X_{0}, \Delta_{0}+B_{0}\right)$. We inductively construct a sequence $X_{i}, \Delta_{i}, B_{i}$ and $D_{i}$ satisfying (1). If $K_{X_{i}}+$ $\Delta_{i}+B_{i}$ is not nef, then there is a divisorial contraction $\phi_{i}$ associated to some $\log$ extremal ray of $K_{X_{i}}+\Delta_{i}+B_{i}$ (clearly $\phi_{i}$ is not of fibre type), and we put $B_{i+1}=\phi_{i_{*}}\left(B_{i}\right), \Delta_{i+1}=\phi_{i_{*}}\left(\Delta_{i}\right)$, and $D_{i+1}=\phi_{i_{*}}\left(D_{i}\right)$. (By [KMM87, 5-1-6] $\left(X_{i+1}, \Delta_{i+1}+B_{i+1}\right)$ is $\mathbb{Q}$-factorial and log terminal.)

Since at each step the Picard number drops by one, this process must terminate at some $i$, and we set $\hat{X}=X_{i}, \hat{B}=B_{i}, \hat{\Delta}=\Delta_{i}$ and $\hat{D}=D_{i}$.

Conditions (1) and (2) are automatic from the construction. (3) follows from the (11.3.3) applied to the pullbacks of the divisors $m\left(K_{X}+\Delta\right)$ and $D_{i}$ to $X_{0}$ (cf. (13.2.4)).

Note that in fact the pair $(\hat{X}, \hat{\Delta}+\hat{B})$ is log terminal; we do not need this.
11.3.3 Lemma. Let $X$ be a proper variety of dimension $n$ and $G_{1}, G_{2}$ two effective nef divisors with the same support. Then $\nu\left(X, G_{1}\right)=\nu\left(X, G_{2}\right)$ and $\kappa\left(X, G_{1}\right)=\kappa\left(X, G_{2}\right)$.

Proof. Let $\nu\left(X, G_{i}\right)=\nu_{i}$ and $\kappa\left(X, G_{i}\right)=\kappa_{i}$. Choose $a_{1}$ so that $a_{1} G_{1}-G_{2}$ is effective.
(1) Let $H$ be any ample divisor. Then

$$
\begin{gathered}
\left(\left(a_{1} G_{1}\right)^{\nu_{2}} \cdot H^{n-\nu_{2}}\right) \geq\left(\left(a_{1} G_{1}\right)^{\nu_{2}-1} \cdot G_{2} \cdot H^{n-\nu_{2}}\right) \\
\vdots \\
\geq\left(G_{2}^{\nu_{2}} \cdot H^{n-\nu_{2}}\right)>0
\end{gathered}
$$

and therefore $\nu_{1} \geq \nu_{2}$.
(2) $\mathrm{H}^{0}\left(m G_{2}\right) \hookrightarrow \mathrm{H}^{0}\left(m a_{1} G_{1}\right)$, therefore $\kappa_{1} \geq \kappa_{2}$.

Now reverse the roles of $G_{1}$ and $G_{2}$.
Now Riemann-Roch for $n \hat{D}$ reads:

$$
\begin{aligned}
\chi(n \hat{D}) & =\frac{n \hat{D} \cdot\left(n \hat{D}-K_{\hat{X}}\right)}{2}+\chi\left(\mathcal{O}_{X}\right) \\
& =\frac{n(n-1 / m)}{2}\left(\hat{D}^{2}\right)+\frac{n}{2} \hat{D} \cdot(\hat{\Delta}+\hat{B})+\chi\left(\mathcal{O}_{X}\right)
\end{aligned}
$$

We know already that $\hat{D}^{2}=0$ and so from now on we can assume $\hat{D} \cdot \hat{\Delta}=0$, since otherwise (11.3.1) follows immediately (because $h^{2}(n \hat{D})=h^{2}\left(K_{\hat{X}}-\right.$ $n \hat{D})=0$ for large $n$, as $G$ is not numerically trivial, and we only need to show $\kappa\left(X, K_{X}+\Delta\right)=1$ ). Since we have chosen $\hat{B}$ so that $\hat{\Delta}$ and $\hat{B}$ have no components in common, this implies that $\hat{\Delta}$ and $\hat{B}$ do not intersect.

Choose an integer $m$ so that $\hat{L}=\mathcal{O}_{\hat{X}}\left(m\left(K_{\hat{X}}+\hat{\Delta}+\hat{B}\right)\right) \in \operatorname{Pic}(\hat{X})$ and $|\hat{L}|$ is non-empty. Note that $\hat{L}$ is nef.
11.3.4 Lemma. There are $X^{\prime}, \Delta^{\prime}, B^{\prime}$ and $D^{\prime}$ satisfying (11.3.2.1-3) and in addition
(4) Every connected component of $B^{\prime}$ is irreducible.

Proof. Pick an irreducible component $S$ of $\hat{B}$. Suppose $S$ meets another component $\hat{S}$ of $\hat{B}$. Now $\nu(X, \hat{L})=1$, so that $\hat{L}^{2}=0$. But $\hat{L}^{2}=\hat{L} \cdot(\hat{D}-\hat{S})+$ $\hat{L} \cdot \hat{S}$, and both terms are non-negative as $\hat{L}$ is nef. It follows that $\hat{L} \cdot \hat{S}=0$ and moreover that $\left(K_{\hat{X}}+\hat{\Delta}+\hat{B}-S\right) \cdot \hat{S}<0$. But then there is a log extremal ray of $\left(K_{\hat{X}}+\hat{\Delta}+\hat{B}-S\right)$ associated to $\hat{S}$, and so a log extremal contraction,
which must be divisorial. Such a contraction decreases the Picard number of $\hat{X}$, and so eventually we may isolate every component of $\hat{B}$.

Pick any prime component $S$ of $B^{\prime}$, and let $U$ be an open subset of $X^{\prime}$ which retracts to $S$ [BPV84, page 27]. Let $L^{\prime}$ be the line bundle $\mathcal{O}_{U}\left(m\left(K_{U}+S\right)\right)=$ $\mathcal{O}_{U}\left(m\left(K_{U}+\Delta^{\prime}+S\right)\right)$.
11.3.5 Lemma. $\left.L^{\prime}\right|_{S}$ is a torsion element of $\operatorname{Pic}(S)$ (i.e some multiple of $\left.L^{\prime}\right|_{S}$ is isomorphic to $\left.\mathcal{O}_{S}\right)$.
Proof. If we apply adjunction to $S$ in $U$, we get

$$
\left.\left(K_{U}+S\right)\right|_{S}=K_{S}+P
$$

where $P=$ Diff is effective. If $P=0$, then $S$ is elliptic or nodal rational and so $K_{S}+P=0$. If $P \neq 0$ then $S$ is a smooth $\mathbb{P}^{1}$.

Now we make a cover of $U$ to improve $S$ and how it sits inside $U$ (compare [Miyaoka88b], where this argument first appears).
11.3.6 Lemma. Let $U$ be a normal analytic space, and $S$ a compact subspace. If the inclusion $i: S \rightarrow U$ induces isomorphisms

$$
i^{*}: H^{j}(U, \mathbb{Z}) \cong H^{j}(S, \mathbb{Z}) \quad \text { for } j=1,2,
$$

then
(1) the kernel of the restriction map

$$
\operatorname{Pic}(U) \longrightarrow \operatorname{Pic}(S)
$$

is a $\mathbb{C}$-vector space. In particular it is divisible, and torsion free.
Moreover if $G$ is a $\mathbb{Q}$-Cartier integral divisor on $U$ such that $\left.G\right|_{S}$ is torsion, then
(2) there is a finite Galois cover $\pi: \tilde{U} \longrightarrow U$, étale in codimension one, such that $\pi^{*} G$ is a Cartier divisor, which restricts to a divisor linearly equivalent to zero on $\pi^{*} S$.

Proof. Compare the cohomology exact sequences of the exponential sequences on $S$ and $U$ :

Now $\operatorname{Pic}(U)=H^{1}\left(U, \mathcal{O}_{U}^{*}\right), \operatorname{Pic}(S)=H^{1}\left(S, \mathcal{O}_{S}^{*}\right)$, and $\beta_{3}$ is just the restriction map. By assumption, $\beta_{1}$ and $\beta_{4}$ are isomorphisms, and so the kernel of $\beta_{3}$ is isomorphic to the kernel of $\beta_{2}$, which in turn is a subvector space of the $\mathbb{C}$-vector space $H^{1}\left(U, \mathcal{O}_{U}\right)$. Hence (1) holds.

For (2), let $r$ be the smallest integer such that $r G$ is Cartier and $\left.r G\right|_{S} \sim 0$. The class of $\left.r G\right|_{S}$ in $H^{2}(S, \mathbb{Z})$ is zero, and as $\beta_{4}$ is an isomorphism, the class of $r G$ is zero in $H^{2}(U, \mathbb{Z})$. As $H^{1}\left(U, \mathcal{O}_{U}\right)$ is divisible, there is a line bundle $M$ on $U$ such that:

$$
\mathcal{O}_{U}(r G) \otimes M^{r}=\mathcal{O}_{U}
$$

We are going to apply (11.3.6.2) to ensure that both the pullback of $K_{X}$ and the class of $S$ are multiples of the same Cartier divisor $\tilde{G}$, which will itself restrict to a divisor linearly equivalent to zero on the pullback of $S$.

As $S$ is irreducible, there is a divisor $D \in\left|m\left(K_{U}+S\right)\right|$ such that $D=e S$ for some positive integer $e$. But then $d S \sim m K_{U}$, where $d=e-m$. Note that either $d$ and $m$ are nonnegative or $d$ is negative, but $-d<m$. Let $c$ be the highest common factor of $m$ and $d$. We may find integers $m^{\prime}, d^{\prime}, b_{1}$ and $b_{2}$ such that:

$$
m=m^{\prime} c, \quad d=d^{\prime} c, \quad c=b_{1} m+b_{2} d
$$

Let $G$ be the Weil divisor $b_{1} S+b_{2} K_{U}$. We have

$$
c\left(S-m^{\prime} G\right)=\left(b_{1} m+b_{2} d\right) S-m\left(b_{1} S+b_{2} K_{U}\right) \sim 0 \sim c\left(K_{U}-d^{\prime} G\right)
$$

and so

$$
c\left(K_{U}+S-\left(m^{\prime}+d^{\prime}\right) G\right) \sim 0
$$

Thus the three divisors

$$
\left.\left(S-m^{\prime} G\right)\right|_{S},\left.\quad\left(K_{U}-d^{\prime} G\right)\right|_{S} \quad \text { and }\left.\quad G\right|_{S}
$$

are all torsion (the third by (11.3.5)). Now we apply (11.3.6.2) three times to these divisors. Thus there is a finite Galois cover $\pi: \tilde{U} \longrightarrow U$, étale in codimension one, such that, if we put $\tilde{S}=\pi^{*} S$ and $\tilde{G}=\pi^{*} G$,

$$
\left.\tilde{G}\right|_{\tilde{S}} \sim 0 \quad \tilde{S} \sim m^{\prime} \tilde{G}, \quad K_{\tilde{U}} \sim d^{\prime} \tilde{G}
$$

and so

$$
\omega_{\tilde{S}}=\left.\mathcal{O}_{\tilde{U}}(\tilde{S})\right|_{\tilde{S}}=\mathcal{O}_{\tilde{S}}
$$

The next lemma shows that $\tilde{S}$ moves in $\tilde{U}$ infinitesimally (cf. [Miyaoka88b, 4.2]). First some notation; let $V$ be an analytic space, and $S$ a Cartier divisor on $V$. Denote by $S_{n}$ the analytic subspace of $V$ defined by the sheaf of ideals $\mathcal{O}_{U}(-n S)$ and set $A_{n}=\operatorname{Spec} \mathbb{C}[\epsilon] /(\epsilon)^{n}$.
11.3.7 Lemma. Let $V$ be a Cohen-Macaulay complex space, and $S$ a divisor on $V$. Assume that $K_{V}$ and $S$ are both multiples $d^{\prime}$ and $m^{\prime}$ of the same Cartier divisor $G$, and that the following three conditions hold
(1) $d^{\prime}+(n-1) m^{\prime} \neq 0$ for any $n \geq 2$,
(2) $\omega_{S} \simeq \mathcal{O}_{S}$,
(3) the restriction $H^{p}\left(S_{n}, \mathcal{O}_{S_{n}}\right) \longrightarrow H^{p}\left(S, \mathcal{O}_{S}\right)$ is surjective for every $p$

Then $S$ moves infinitesimally in $V$, to any order.
Proof. We prove the following statements by induction on $n$.
$(\mathrm{i})_{n}$ There are proper flat morphisms $\xi_{i}: S_{i} \longrightarrow A_{i}(i \leq n)$ such that the following diagram is commutative

(ii) $n_{n}$ The sheaves $R^{p} \xi_{n *} \mathcal{O}_{S_{n}}$ are locally free.
(iii) ${ }_{n} \omega_{S_{n}} \simeq \mathcal{O}_{S_{n}}$.

Note that if (i) $)_{n}$ holds for every $n$, then $S$ moves infinitesimally to any order, by definition.

For $n=1$, we take $\xi_{1}$ to be the structure map. Then (ii) ${ }_{1}$ is automatic, and (iii) ${ }_{1}$ is just (2).

Otherwise suppose that all three statements are true for all integers less than $n$. As $K_{V}+(n-1) S$ is Cartier and $S_{n-1}$ is Cohen Macaulay (it is a Cartier divisor in a Cohen Macaulay scheme), we may apply adjunction to $S_{n-1}$ :

$$
\begin{aligned}
\omega_{S_{n-1}} & =\omega_{V}((n-1) S) \otimes \mathcal{O}_{S_{n-1}} \\
& =\mathcal{O}_{S_{n-1}}\left(\left(d^{\prime}+(n-1) m^{\prime}\right) G\right)
\end{aligned}
$$

On the other hand (iii) ${ }_{n-1}$ implies that $\omega_{S_{n-1}}$ is linearly equivalent to zero. We may apply (11.3.6) (1) to $S$ and $S_{n-1}$ to deduce that $G$ is linearly equivalent to zero on $S_{n-1}$. In particular $\mathcal{O}_{S_{n-1}} \otimes \mathcal{O}_{V}(-S) \simeq \mathcal{O}_{S_{n-1}}$.

Consider the exact sequence of sheaves on $V$,

$$
0 \longrightarrow \mathcal{K} \longrightarrow \mathcal{O}_{S_{n}} \longrightarrow \mathcal{O}_{S} \longrightarrow 0
$$

where $\mathcal{K}$ is defined by exactness. It is clear that the support of $\mathcal{K}$ is $S_{n-1}$. In fact

$$
\mathcal{O}_{S}=\mathcal{O}_{V} / \mathcal{O}_{V}(-S) \quad \mathcal{O}_{S_{n}}=\mathcal{O}_{V} / \mathcal{O}_{V}(-(n+1) S)
$$

and so $\mathcal{K} \cong \mathcal{O}_{S_{n-1}} \otimes \mathcal{O}_{V}(-S)$ as a sheaf of $\mathcal{O}_{V}$-modules. Now we have shown that this is the trivial line bundle on $S_{n-1}$.

Let $e$ be the image of the global section 1 of the sheaf $\mathcal{K}$ in the vector space $H^{0}\left(S_{n}, \mathcal{O}_{S_{n}}\right)$. Define a $\mathbb{C}$-algebra homomorphism from $\mathbb{C}[\epsilon] /(\epsilon)^{n}$ to $H^{0}\left(S_{n}, \mathcal{O}_{S_{n}}\right)$, by sending $\epsilon$ to $e$. This gives $H^{0}\left(S_{n}, \mathcal{O}_{S_{n}}\right)$ a flat $\mathbb{C}[\epsilon] /(\epsilon)^{n}$ module structure, which since $A_{n}$ is affine, is equivalent to a proper flat morphism $\xi_{n}: S_{n} \longrightarrow A_{n}$. It is not hard, from the definition of $\xi_{n}$, to check that the diagram

commutes. This proves $(\mathrm{i})_{n}$.
Condition (3) now implies (ii) $n_{n}$ (see for example [Hartshorne77, III 12.11]). It follows by duality, that $R^{p} \xi_{n *} \omega_{S_{n}}$ are also locally free, for every $p$. (Unfortunately this seems to require relative duality theory, see e.g. [Hartshorne66].) As $\omega_{S}$ is isomorphic to the trivial line bundle, $\xi_{n *} \omega_{S_{n}}$ has a global non vanishing section, which we may pullback to $\omega_{S_{n}}$. Thus $\omega_{S_{n}}$ is trivial also, which is $(\mathrm{iii})_{n}$.
11.3.8 Example. There is an interesting example which indicates the necessity for the somewhat strange assumptions of (11.3.7). Take $X$ to be a $\mathbb{P}^{1}$-bundle over an elliptic curve, given by the unique rank two vector bundle of degree zero which does not split. $X$ has a unique section $S$ of selfintersection zero, which does not move. However it does move to first order. Of course there is no divisor $G$ such that both the class of the curve and its dualizing sheaf are multiples of $G$.
11.3.9. Now we check that the conditions of (11.3.7) apply to $\tilde{S}$ in $\tilde{U}$. In fact (1) follows as $m^{\prime}$ is always positive, and if $d^{\prime}$ is negative, $-d^{\prime}<m^{\prime}$, (2) has already been verified, and so we are left with (3). But as $\tilde{S}$ is a curve, certainly

$$
H^{1}\left(\tilde{S}_{n}, \mathcal{O}_{\tilde{S}_{n}}\right) \longrightarrow H^{1}\left(\tilde{S}, \mathcal{O}_{\tilde{S}}\right),
$$

is surjective, as the obstruction is the second cohomology of the kernel of the natural map $\mathcal{O}_{\tilde{S}_{n}} \longrightarrow \mathcal{O}_{\tilde{S}}$, which always vanishes. This leaves

$$
H^{0}\left(\tilde{S}_{n}, \mathcal{O}_{\tilde{S}_{n}}\right) \longrightarrow H^{0}\left(\tilde{S}, \mathcal{O}_{\tilde{S}}\right) \simeq \mathbb{C},
$$

which is again certainly surjective.
Now we are in a position to finish the proof of (11.3.1). Let $G$ be the Galois group of the cover $\tilde{U} \longrightarrow U$ of degree $r$. The Cartier divisor $(r S)_{n}$ pulls back,
under $\pi$, to the Cartier divisor $\tilde{S}_{n r}$. Thus $\tilde{S}_{n r}$ descends to $(r S)_{n}$, and moreover $G$ acts naturally on $H^{0}\left(\tilde{S}_{n r}, \mathcal{O}_{\tilde{S}_{n r}}\right)$. But this may be identified, via $\xi_{n r}$, with $\mathbb{C}[\epsilon] /(\epsilon)^{n r}$. It follows that $(r S)_{n}$ maps to $A_{n s}=\operatorname{Spec}\left(\mathbb{C}[\epsilon] /(\epsilon)^{n r}\right)^{G}$, for some $s$ dividing $r$. Since the Hilbert scheme is of finite type we are done.

# 12. SEMI LOG CANONICAL SURFACES 

Dan Abramovich, Lung-Ying Fong,<br>János Kollár, and James MCKernan

### 12.1 Introduction

In this chapter we collect together some results concerning semi log canonical surfaces (see (12.2) for the definitions and basic properties). The first of these is $\log$ abundance for semi log canonical surfaces in the cases $\nu=0$ or $\nu=1$.
12.1.1 Theorem. Let $S$ be a reduced projective surface and let $\Delta$ be a $\mathbb{Q}$-Weil divisor on $S$. Assume that $K_{S}+\Delta$ is $\mathbb{Q}$-Cartier, nef and semi log canonical and $\nu\left(S, K_{S}+\Delta\right)=0$ or 1 .

Then the linear system $\left|m\left(K_{S}+\Delta\right)\right|$ is base point free for suitable $m>0$ (and in particular $\nu\left(S, K_{S}+\Delta\right)=\kappa\left(S, K_{S}+\Delta\right)$ ).

The idea is to show that we can descend sections to $S$ from the normalization of $S$ (here we use (11.1.3)). In both cases the arguments are a little delicate; we have to analyze carefully the patching data.

The second result is a version of (1.13) (which is proved in (12.5)).
12.1.2 Theorem. Let $S$ be a reduced projective surface with semi log canonical singularities. Then the natural map induced by $\mathbb{C}_{S} \subset \mathcal{O}_{S}$

$$
i_{p}: H^{p}\left(S, \mathbb{C}_{S}\right) \longrightarrow H^{p}\left(S, \mathcal{O}_{S}\right) \quad \text { is surjective for every } p
$$

When $S$ is smooth (12.1.2) is a standard result. Therefore we just need to analyze how the cohomology of $S$ differs from the cohomology of a resolution. We split this analysis into two steps; in one step we consider how to resolve the bad singularities at isolated points of $S$, and in the other step we remove the one dimensional singular locus via a finite map. However we introduce a new twist; rather than first normalizing $S$ for the second step, which loses too much information about the singularities of $S$, we make $S$ as nice as possible by altering $S$ at a finite set of points, and then normalize.
S. M. F.

### 12.2 BASIC RESULTS

We collect together here some of the properties of semi log canonical surface singularities.

Let $X$ be a scheme with at worst double normal crossings in codimension one. The next set of definitions introduces the appropriate notion of log canonical (these definitions were given in [KSB88] for surfaces).

### 12.2.1 Definition.

(1) An $n$-dimensional singularity $(x \in X)$ is called a double normal crossing point, resp. a pinch point if it is analytically (or formally) isomorphic to
$\left(0 \in\left(x_{0} x_{1}=0\right)\right) \subset\left(0 \in \mathbb{C}^{n+1}\right)$ resp. $\left(0 \in\left(x_{0}^{2}=x_{1} x_{2}^{2}\right)\right) \subset\left(0 \in \mathbb{C}^{n+1}\right)$.
(2) An $n$-fold $X$ is semismooth if every closed point $(x \in X)$ is either smooth or double normal crossing point or pinch point. The singular locus of $X$ is then a smooth $(n-1)$-fold $D_{X}$. The normalization $\nu: X^{\nu} \rightarrow X$ is smooth and $D_{\nu}=\nu^{-1}\left(D_{X}\right) \rightarrow D_{X}$ is a double cover ramified along the pinch locus.
(3) A morphism $f: Y \rightarrow X$ is called a semiresolution if $f$ is proper, $Y$ is semismooth, no component of $D_{Y}$ is $f$-exceptional, and there is a codimension two closed subset $S \subset X$ such that $f \mid f^{-1}(X \backslash S)$ : $f^{-1}(X \backslash S) \rightarrow X \backslash S$ is an isomorphism.
(4) Let $X$ be a reduced scheme, $\Delta \subset X$ a $\mathbb{Q}$-Weil divisor (cf. (16.2)). Let $f: Y \rightarrow X$ be a semiresolution with exceptional divisors $E$ and exceptional set $E x(f) \subset Y$.
$f$ is a good semiresolution (resp. a good divisorial semiresolution) of $\Delta \subset X$ if the union $E \cup D_{Y} \cup f_{*}^{-1}(\Delta)\left(\right.$ resp. $\left.E x(f) \cup D_{Y} \cup f_{*}^{-1}(\Delta)\right)$ is a divisor with global normal crossings on $Y$.
(5) Let $S$ be a reduced surface. A semiresolution $f: T \rightarrow S$ is minimal if $\omega_{T}$ is $f$-nef. (In the nonnormal case, minimal resolutions are not unique.)
(6) Let $X$ be a reduced $S_{2}$ scheme, $\Delta \subset X$ a boundary (i.e., a $\mathbb{Q}$-Weil divisor $\Delta=\sum d_{i} \Delta_{i}$ with $0 \leq d_{i} \leq 1$ ). We say that $K_{X}+\Delta$ is semi log terminal (resp. divisorial semi log terminal, resp. semi log canonical) (frequently abbreviated as slt resp. dslt resp. slc) if it is $\mathbb{Q}$-Cartier and there is a good semiresolution (resp. a good divisorial semiresolution, resp. a good semiresolution) $f: Y \rightarrow X$ of $\Delta \subset X$ such that:

$$
K_{Y}+f_{*}^{-1}(\Delta)=f^{*}\left(K_{X}+\Delta\right)+\sum a_{i} E_{i},
$$

where the $E_{i}$ are the $f$-exceptional divisors and all $a_{i}>-1$ (resp. $a_{i}>-1$ resp. $a_{i} \geq-1$ ). We leave it to the reader to formulate the analogous definition of the various flavors of semi log terminal.
(7) Let $f: Y \rightarrow X$ be a semiresolution. We say $X$ has semirational singularities, if $f_{*} \mathcal{O}_{Y}=\mathcal{O}_{X}$ and $R^{i} f_{*} \mathcal{O}_{Y}=0$ for $i>0$. As in the normal case, this is independent of the semiresolution chosen.
(8) A scheme $X$ (over an algebraically closed field) is called seminormal if the following condition holds:

Every finite and surjective morphism $X^{\prime} \rightarrow X$ which is one-to-one on closed points is an isomorphism.
12.2.2 Notation. Let $(X, \Delta)$ be slc. Let $\mu: X^{\mu} \longrightarrow X$ be the normalization. Let $D \subset X$ (resp. $D_{\mu} \subset X^{\mu}$ ) be the double intersection locus. Thus $\mu \mid D_{\mu}$ : $D_{\mu} \longrightarrow D$ is a double cover. Let $\Theta=\mu^{-1} \Delta+D_{\mu}$. Thus

$$
K_{X^{\mu}}+\Theta=\mu^{*}\left(K_{X}+\Delta\right)
$$

The irreducible components of $X^{\mu}$ are frequently denoted by $X_{i}$ and then $\Theta_{i}$ denotes the restriction of $\Theta$ to $X_{i}$.
12.2.3 Proposition. [vanStraten87] Let $S$ be a surface which is semismooth in codimension one. Then $S$ has a minimal semiresolution. If $\Delta \subset S$ is a Weil divisor then $(S, \Delta)$ has a good semiresolution.

Proof. Let $S$ be a surface, with normal crossings in codimension one, and choose a good resolution $\left(T_{0}, D_{0}\right)$ of the pair $\left(S^{\mu}, D_{\mu}\right)$. If $\Delta=\emptyset$ then $D_{\mu}$ is reduced and we may assume in addition that $K_{T_{0}}+D_{0}$ is nef on $T_{0} / S^{\mu}$. The $\operatorname{map} D_{\mu} \longrightarrow D_{S}$ is two-to-one, and defines an involution $\tau$ on $D_{0}$. It is easy to see (cf. [Artin70] for the general theory) that one can find an analytic (or algebraic) space $T$, which is obtained from $T_{0}$ by gluing together points of $D_{0}$ that are conjugate under the involution $\tau$. Moreover it is not hard to see that $T$ is semismooth; pinch points correspond to fixed points of the involution $\tau$. There is a morphism $f: T \longrightarrow S$ with fibres which are either points or curves. Thus $f$ is projective, hence $T$ is also projective and so $f$ is a semiresolution.

The following is clear from the definitions (cf. (2.6)):
12.2.4 Proposition. Notation as above. Then

$$
\operatorname{discrep}(X, \Delta)=\operatorname{discrep}\left(X^{\mu}, \Theta\right)
$$

It might seem from (12.2.4) that one could define the semi log versions of lt, lc etc. by requiring the corresponding notion to hold for the normalization. However, $K_{X}+\Delta$ is usually not $\mathbb{Q}$-Cartier even when $\Delta=\emptyset$ and $\left(X^{\mu}, \Theta\right)$ is log canonical. In dimension two one can give the following necessary (and sufficient) condition.
12.2.5 Proposition. Let $(S, \Delta)$ be a slc surface. Let $D_{1} \subset S$ be a double curve such that $\mu^{-1}\left(D_{1}\right)=D_{1}^{\prime} \cup D_{1}^{\prime \prime}$ has two components. Then (see (16.6) for the definition of Diff)

$$
\operatorname{Diff}_{D_{1}^{\prime}}\left(\Theta-D_{1}^{\prime}\right)=\operatorname{Diff}_{D_{1}^{\prime \prime}}\left(\Theta-D_{1}^{\prime \prime}\right) .
$$

Proof. Let $S_{1}, S_{2}$ be analytic neighborhoods of $D_{1}^{\prime}, D_{1}^{\prime \prime}$ respectively. We abuse notation, and identify $S_{1}$ and $S_{2}$ with their images under $\mu$. Now we may compute the different at any point of $D_{1}^{\prime}$ or $D_{1}^{\prime \prime}$, on the surface $S$, by first restricting to $S_{1}$ or $S_{2}$. In either case this is equivalent to restricting $K_{S}+\Delta$ to the double curve $D_{1}$.
12.2.6 Corollary. Let $(S, \Delta)$ be a germ of a slc surface. Assume that $S^{\mu}$ has two irreducible components $S_{1}^{\mu}, S_{2}^{\mu}$. Then

$$
\left(S_{1}^{\mu}, \Theta_{1}\right) \cong\left(\mathbb{C}^{2}, \mathbb{C}\right) \quad \Leftrightarrow \quad\left(S_{2}^{\mu}, \Theta_{2}\right) \cong\left(\mathbb{C}^{2}, \mathbb{C}\right)
$$

Proof. Note that by $(16.6)\left(S_{i}, \Theta_{i}\right)$ is isomorphic to $\left(\mathbb{C}^{2}, \mathbb{C}\right)$ iff $\Theta_{i}$ is irreducible and the different is zero.
12.2.7 Corollary. Let $(S, B)$ be a germ of a slt surface. Then $S$ has one or two irreducible components.

Proof. Assume that $S$ has at least three irreducible components. Then there is a component $S_{1}$ which intersects at least two other components along curves. Thus $\Theta_{i}=\Theta \mid S_{i}^{\mu}$ contains at least two reduced curves. By Chapter 3, this implies that $\left(S_{i}^{\mu}, \Theta_{i}\right)$ is not lt.
12.2.8 Proposition - Definition. Let $(S, \Delta)$ be a germ of an slc surface. Let $f: T \rightarrow S$ be a minimal semiresolution (of $S$ ). Let $E_{i} \subset T$ be the exceptional divisors. Then

$$
\begin{equation*}
K_{T}+f_{*}^{-1}(\Delta)=f^{*}\left(K_{S}+\Delta\right)+\sum a_{i} E_{i}, \tag{1}
\end{equation*}
$$

where $0 \geq a_{i} \geq-1$. Let $E=\sum_{a_{i}=-1} E_{i}$.
(2) $R^{1} f_{*} \mathcal{O}_{T}(-E)=0$.
(3) If $(S, \Delta)$ is not semirational then $\Delta=\emptyset$ and $S$ is either simple elliptic, a cusp or a degenerate cusp; where we define $S$ to be
(i) simple elliptic, if $E=E x(f)$ is a smooth elliptic curve, and $S$ is normal,
(ii) a cusp (resp. degenerate cusp), if $S$ is normal (resp. not normal, but $T$ has no pinch points, locally about $E$ ), if $E=E x(f)$ is a cycle of $\mathbb{P}^{1}$ or a nodal $\mathbb{P}^{1}$.

Proof. Let $\nu: T^{\nu} \longrightarrow T$ be the normalization of $T$. We get a commutative diagram

Now $g: T^{\nu} \longrightarrow S^{\mu}$ is a resolution of $S^{\mu}$. Thus

$$
K_{T^{\nu}}+g_{*}^{-1}(\Theta)=g^{*}\left(K_{S^{\mu}}+\Theta\right)+\sum a_{i} F_{i}
$$

where $F_{i}$ are the exceptional divisors of $g$ and $0 \geq a_{i}$ follows from (2.19).
Let $F=\sum_{a_{i}=-1} F_{i}$. Then $f^{*} E=F$, and so to show that $R^{1} f_{*} \mathcal{O}_{T}(-E)=$ 0 , it is enough to show that $R^{1} g_{*} \mathcal{O}_{T^{\nu}}(-F)=0$, as the morphisms $\nu$ and $\mu$ are finite. But as

$$
-F=K_{T^{\nu}}+\left(g_{*}^{-1}(\Theta)+\sum_{a_{i}>-1}-a_{i} F_{i}\right)-g^{*}\left(K_{S^{\mu}}+\Theta\right)
$$

this follows by Kawamata-Viehweg vanishing [KMM87, 1-2-3].
Now if $S$ is not semirational, $h^{1}\left(\mathcal{O}_{E}\right) \geq 1$, by (2). Applying adjunction to $E$, we have:

$$
K_{E}=\left(K_{T}+E\right)\left|E=\sum_{0 \geq a_{i}>-1}\left(a_{i} E_{i}-f_{*}^{-1}(\Delta)\right)\right| E
$$

which is negative unless $E=E x(f)$ and $\Delta=\emptyset$. Thus $H^{1}\left(\mathcal{O}_{E}\right)=0$ unless $E=E x(f)$ and $\Delta=\emptyset$. In the latter case $E$ has arithmetic genus one, and so it is an elliptic curve, a cycle of $\mathbb{P}^{1}$ or a nodal $\mathbb{P}^{1}$. Therefore if $S$ is not normal then $D^{\mu}$ has two components on every component of $S^{\mu}$ and every ( $S^{\mu}, D_{\mu}$ ) falls to case (9) of Figure 3 in the classification of Chapter 3. Thus $S$ is a degenerate cusp. This proves (3).
12.2.9 Definition. Let $(C, \Delta)$ be a semi $\log$ canonical curve and $\Delta$ a $\mathbb{Q}$-divisor.

Let $n: \bar{C}=\cup C_{i} \rightarrow C$ be the normalization and define $\Delta_{i}$ by

$$
n^{*}\left(K_{C}+\Delta\right) \mid C_{i}=K_{C_{i}}+\Delta_{i} .
$$

Assume that $m\left(K_{C_{i}}+\Delta_{i}\right)$ is an integral divisor. For every $P \in\left\llcorner\Delta_{i}\right\lrcorner$ let $z_{P}$ be a local parameter at $P$. A section $s_{i} \in \Gamma\left(C_{i}, \mathcal{O}\left(m\left(K_{C_{i}}+\Delta_{i}\right)\right)\right)$ is normalized if $s_{i}-\left(d z_{P} / z_{P}\right)^{m}$ vanishes at $P$. This is easily seen to be independent of the choice of $z_{P}$.

A section $s \in \Gamma\left(C, \mathcal{O}\left(m\left(K_{C}+\Delta\right)\right)\right)$ is normalized if $n^{*}(s) \mid C_{i}$ is normalized for every $i$.

On the nodal curve $(x y=0) \subset \mathbb{C}^{2}$ consider the 1 -form $\sigma=d x / x=-d y / y$. Even powers of $\sigma$ are normalized and there are no normalized sections if $m$ is odd.

All normalized sections form an affine subspace in the space of sections. This will be denoted by

$$
\Gamma^{n}\left(C, \mathcal{O}\left(m\left(K_{C}+\Delta\right)\right)\right) .
$$

12.2.9.1 Complement. If $C_{i}$ is such that $\left\llcorner\Delta_{i}\right\lrcorner=0$ then $C_{i}$ is a smooth connected component of $C$ and the above definition imposes no restrictions on sections of $\mathcal{O}\left(m\left(K+\Delta_{i}\right)\right)$. For our purposes it will be convenient to make the following convention. Assume that $C_{i}$ is an elliptic curve such that $\Delta_{i}=0$. Aut $(C)$ acts trivially on $H^{0}\left(C, \mathcal{O}_{C}\left(12 K_{C}\right)\right)$. We fix a nonzero section for every elliptic curve and call it (and its powers in $H^{0}\left(C, \mathcal{O}_{C}\left(12 m K_{C}\right)\right)$ ) normalized.
12.2.10 Definition. Let $(X, \Delta)$ be an slc surface. As in (12.2.2) let $n$ : $\left(X^{\mu}, \Theta\right) \rightarrow(X, \Delta)$ be the normalization. As section $s \in \Gamma\left(X, \mathcal{O}\left(m\left(K_{X}+\Delta\right)\right)\right)$ is normalized if

$$
n^{*} s \mid\llcorner\Theta\lrcorner \in \Gamma\left(\llcorner\Theta\lrcorner, \mathcal{O}\left(m\left(K_{\llcorner\Theta\lrcorner}+\operatorname{Diff}(\Theta-\llcorner\Theta\lrcorner)\right)\right)\right)
$$

is normalized.
All normalized sections form an affine subspace $\Gamma^{n}\left(X, \mathcal{O}\left(m\left(K_{X}+\Delta\right)\right)\right)$ in the space of all sections.
12.2.11 Proposition. Let $(C, \Delta)$ be an slc curve and let $m$ be a natural number such that $m \Delta$ is integral. Then
(12.2.11.1) $\Gamma^{n}\left(C, \mathcal{O}\left(2 m\left(K_{C}+\Delta\right)\right)\right)=\prod_{i} \Gamma^{n}\left(C_{i}, \mathcal{O}\left(2 m\left(K_{C_{i}}+\Delta_{i}\right)\right)\right)$;
(12.2.11.2) If $K_{C}+\Delta$ is nef then $\Gamma^{n}\left(C, \mathcal{O}\left(12 m\left(K_{C}+\Delta\right)\right)\right)$ generates $\mathcal{O}\left(12 m\left(K_{C}+\Delta\right)\right)$.

Proof. The first part is clear. Using the first part, it is sufficient to prove the second for $C$ irreducible and smooth.

We distinguish two cases:
(12.2.11.3) $\operatorname{deg}\left(K_{C}+\Delta\right)=0$. Then either $g(C)=1$ and $\Delta=0$ or $g(C)=$ 0 and $\llcorner\Delta\lrcorner$ is at most two points of $C . \mathcal{O}\left(12 m\left(K_{C}+\Delta\right)\right)$ has one section (up to scalars) and a suitable multiple is normalized if $\llcorner\Delta\lrcorner$ is at most one point. If $\llcorner\Delta\lrcorner=\{0, \infty\}$ then $(d z / z)^{12 m}$ is normalized.
(12.2.11.4) $\operatorname{deg}\left(K_{C}+\Delta\right)>0$. Let $P$ be any point different from $\llcorner\Delta\lrcorner$. Consider the exact sequence
$0 \rightarrow \mathcal{O}\left(12 m\left(K_{C}+\Delta\right)-\llcorner\Delta\lrcorner-P\right) \rightarrow \mathcal{O}\left(12 m\left(K_{C}+\Delta\right)\right) \rightarrow \mathbb{C}(P)+\mathbb{C}(\llcorner\Delta\lrcorner) \rightarrow 0$.

Since

$$
\begin{aligned}
& \operatorname{deg}\left(12 m\left(K_{C}+\Delta\right)-\llcorner\Delta\lrcorner-P\right) \\
& =\operatorname{deg}\left(K_{C}+11 m\left(K_{C}+\Delta\right)\right)+\operatorname{deg}\left((m-1)\left(K_{C}+\Delta\right)+\{\Delta\}\right)-1 \\
& \geq \operatorname{deg} K_{C}+11-1=\operatorname{deg} K_{C}+10
\end{aligned}
$$

we conclude that

$$
H^{0}\left(C, \mathcal{O}\left(12 m\left(K_{C}+\Delta\right)\right)\right) \rightarrow H^{0}(C, \mathbb{C}(P)+\mathbb{C}(\llcorner\Delta\lrcorner))
$$

is surjective.

### 12.3 The reduced boundary of lC surfaces

Let $(S, \Theta)$ be an lc surface. Our aim is to analyze $\llcorner\Theta\lrcorner$ in the cases when $\nu(S, \Theta) \in\{0,1\}$.
12.3.1 Proposition. [Shokurov91, 6.9] Let $(S, \Theta)$ be a proper lc surface. Assume that $K+\Theta \equiv 0$. Then $(S, \Theta)$ satisfies one of the following conditions:
(1) $\llcorner\Theta\lrcorner$ is connected and for every $C \in\llcorner\Theta\lrcorner$ the pair $(C, \operatorname{Diff}(\Theta-C))$ is not klt, (i.e., $\operatorname{Diff}(\Theta-C)$ contains a point with multiplicity 1.)
(2) $\llcorner\Theta\lrcorner$ is irreducible and for $C=\llcorner\Theta\lrcorner$ the pair $(C, \operatorname{Diff}(\Theta-C))$ is klt.
(3) $\llcorner\Theta\lrcorner$ has two connected components, for every $C \subset\llcorner\Theta\lrcorner$ the pair $(C, \operatorname{Diff}(\Theta-C))$ is klt and there is a morphism onto a curve $g: S \rightarrow B$ such that $\llcorner\Theta\lrcorner$ consists of two sections of $g$. ( $B$ is either rational or elliptic.)

Proof. Let $h: S^{\prime} \rightarrow S$ be an lt modification of $S$ and let $K+\Theta^{\prime}=h^{*}(K+\Theta)$. Then ( $S^{\prime}, \Theta^{\prime}$ ) is lt and it is sufficient to prove that the result holds for ( $S^{\prime}, \Theta^{\prime}$ ). In this case ( $C, \operatorname{Diff}\left(\Theta^{\prime}-C\right)$ ) is not klt iff $C$ intersects another irreducible component of $\left\llcorner\Theta^{\prime}\right\lrcorner$.

We prove a stronger relative version:
12.3.2 Proposition. Let $(S, \Theta)$ be a log terminal surface. Let $f: S \rightarrow R$ be a proper morphism with connected fibers. Assume that $K+\Theta$ is numerically $f$-trivial. Let $r \in R$ be arbitrary. Then one of the following holds:
(1) $\llcorner\Theta\lrcorner$ is connected in a neighborhood of $f^{-1}(r)$;
(2) $\llcorner\Theta\lrcorner$ has two connected components in a neighborhood of $f^{-1}(r)$, both components are smooth and there is a morphism onto a curve $g: S / R \rightarrow B / R$ such that $\llcorner\Theta\lrcorner$ consists of two sections of $g$.

Proof. If $f$ is birational then (17.4) implies that we have (1). Thus we may assume that $f$ has positive dimensional fibers and that $\llcorner\Theta\lrcorner \neq \emptyset$.

We apply the $(K+\Theta-\epsilon\llcorner\Theta\lrcorner)$-MMP on $S / R$ for $0<\epsilon \ll 1$. The end result is a proper birational morphism $p: S / R \rightarrow Z / R$ such that $K_{Z}+p(\Theta)$ is lc and $K_{Z}+p(\Theta)-\epsilon\llcorner p(\Theta)\lrcorner$ is lt. We claim that

$$
p(\llcorner\Theta\lrcorner)=\llcorner p(\Theta)\lrcorner .
$$

Indeed, since $K+\Theta$ is numerically $f$-trivial, $K=p^{*}\left(K_{Z}+p(\Theta)\right)-\Theta$. If $z \in p(\llcorner\Theta\lrcorner)-\llcorner p(\Theta)\lrcorner$ then

$$
K=p^{*}\left(K_{Z}+p(\Theta)\right)-\Theta=p^{*}\left(K_{Z}+p(\Theta)-\epsilon\llcorner p(\Theta)\lrcorner\right)-\Theta
$$

in a neighborhood of $p^{-1}(z)$, which shows that $K_{Z}+p(\Theta)-\epsilon\llcorner p(\Theta)\lrcorner$ is not lt at $z$, a contradiction. In particular $\llcorner p(\Theta)\lrcorner \neq \emptyset$. By (17.4) the fibers of $\llcorner\Theta\lrcorner \rightarrow\llcorner p(\Theta)\lrcorner$ are connected, hence $\llcorner p(\Theta)\lrcorner$ is connected iff $\llcorner\Theta\lrcorner$ is connected.

Now we distinguish several cases.
(i) $K_{Z}+p(\Theta)-\epsilon\llcorner p(\Theta)\lrcorner$ is numerically trivial over $R$. This can only happen if the fibers of $Z \rightarrow R$ are one dimensional and $\llcorner p(\Theta)\lrcorner$ is the union of some fibers, thus $\llcorner p(\Theta)\lrcorner$ is connected near any fiber. Otherwise there is a $\left(K_{Z}+p(\Theta)-\epsilon\llcorner p(\Theta)\lrcorner\right)$-extremal contraction $u: Z / R \rightarrow V / R$. Here there are two subcases:
(ii) $u$ contracts $Z$ to a point. Then $\rho(Z)=1$, hence any two curves in $Z$ intersect. Thus $\llcorner p(\Theta)\lrcorner$ is connected.
(iii) $u$ contracts $Z$ to a curve and the generic fiber is $\mathbb{P}^{1}$. Therefore $\llcorner p(\Theta)\lrcorner$ intersects the generic fiber in at most two points. For any $v \in V$, the fiber $u^{-1}(v) \subset Z$ is an irreducible curve. Thus if $\llcorner p(\Theta)\lrcorner$ is not connected in the neighborhood of a fiber of $Z \rightarrow S$ then $\llcorner p(\Theta)\lrcorner$ is the union of two sections of $u$ near that fiber. Thus $\llcorner\Theta\lrcorner$ also has two connected components.
In order to prove (2), consider the morphism $u \circ p: S \rightarrow V$. In a neighborhood of $(u \circ p)^{-1}(v),\llcorner\Theta\lrcorner$ consists of two sections and possibly some other curves $C=\cup C_{i} \subset(u \circ p)^{-1}(v)$ which are $p$-exceptional. If $C$ is not empty then $(u \circ p)^{-1}(v)-C$ is contractible, and the resulting contraction contradicts (17.4). Thus $C$ is empty and (2) holds.

As a straightforward corollary we obtain:
12.3.3 Theorem. Let $(S, \Delta)$ be a proper, connected slc surface such that $K+\Delta \equiv 0$. Let $\left(S_{i}, \Theta_{i}\right)$ be the irreducible components of the normalization. Then one of the following conditions is satisfied:
(1) $\left\llcorner\Theta_{i}\right\lrcorner$ is connected for every $i$ and for every irreducible curve $C \subset\left\llcorner\Theta_{i}\right\lrcorner$ the different $\left(C, \operatorname{Diff}\left(\Theta_{i}-C\right)\right)$ is not klt.
(2) For every $i$ and for every irreducible curve $C \subset\left\llcorner\Theta_{i}\right\lrcorner$ the different $\left(C, \operatorname{Diff}\left(\Theta_{i}-C\right)\right)$ is klt.

The combinatorial description of the intersections of the irreducible components of $S$ is very subtle in case (1). (See [Friedman-Morrison83] for an overview of the special case of semistable degenerations of surfaces.) In the second case the combinatorics is easy but we need further information about the relationship between the two components of $\left\llcorner\Theta_{i}\right\lrcorner$.
12.3.4 Theorem. Let $(S, \Theta)$ be an lc surface. Let $f: S \rightarrow B$ be a proper morphism onto a curve, with connected fibers. Assume that $K+\Theta$ is numerically $f$-trivial and $\llcorner\Theta\lrcorner \supset C_{1} \cup C_{2}$ where the $C_{i}$ are sections of $f$. Let $f_{i}=f \mid C_{i}$. Then
(1) $\left(f_{1}\right)_{*} \operatorname{Diff}_{C_{1}}\left(\Theta-C_{1}\right)=\left(f_{2}\right)_{*} \operatorname{Diff}_{C_{2}}\left(\Theta-C_{2}\right)$; let us call this $\mathbb{Q}$-divisor $P$.
(2) For some $m>0$ we have an isomorphism $\psi: f^{*} \mathcal{O}_{B}(m K+m P) \cong$ $\mathcal{O}_{S}(m K+m \Theta)$.
(3) Let $\psi_{i}$ denote the composite isomorphism

$$
\begin{aligned}
\psi_{i}: \mathcal{O}_{B}(m K+m P) & \cong f_{*}\left(f^{*} \mathcal{O}_{B}(m K+m P)\right) \\
& \cong \\
& \cong f_{*} \mathcal{O}_{S}(m K+m \Theta) \\
& \cong f_{*}\left(\mathcal{O}_{S}(m K+m \Theta) \mid C_{i}\right) \\
& \cong\left(f_{i}\right)_{*} \mathcal{O}_{C_{i}}\left(m K+m \operatorname{Diff}\left(\Theta-C_{i}\right)\right)
\end{aligned}
$$

Then
$\psi_{2} \circ \psi_{1}^{-1}:\left(f_{1}^{-1} \circ f_{2}\right)^{*} \mathcal{O}_{C_{1}}\left(m K+m \operatorname{Diff}\left(\Theta-C_{1}\right)\right) \rightarrow \mathcal{O}_{C_{2}}\left(m K+m \operatorname{Diff}\left(\Theta-C_{2}\right)\right)$
and the natural isomorphism
$\left(f_{1}^{-1} \circ f_{2}\right)_{*}:\left(f_{1}^{-1} \circ f_{2}\right)^{*} \mathcal{O}_{C_{1}}\left(m K+m \operatorname{Diff}\left(\Theta-C_{1}\right)\right) \rightarrow \mathcal{O}_{C_{2}}\left(m K+m \operatorname{Diff}\left(\Theta-C_{2}\right)\right)$
differ by the sheaf multiplication ( -1 ).
Proof. Let $h:\left(S^{\prime}, \Theta^{\prime}\right) \rightarrow(S, \Theta)$ be a proper morphism such that $K+\Theta^{\prime} \equiv$ $h^{*}(K+\Theta)$. Then the theorem holds for $(S, \Theta)$ iff it holds for $\left(S^{\prime}, \Theta^{\prime}\right)$. Thus as in (11.2.4) we may reduce to the case when $S$ is smooth, and then by contracting ( -1 )-curves in the fibers we may assume that $f: S \rightarrow B$ is a $\mathbb{P}^{1}$-bundle. Thus $\Theta$ consists of two sections and some fibers (with coefficients), which clearly implies (1). (2) and (3) are not affected by the vertical components of $\Theta$, thus we may even assume that $\Theta=C_{1} \cup C_{2}$. By further elementary
transformations we may also assume that $C_{1}$ and $C_{2}$ are disjoint. It is now clear that

$$
\psi: \mathcal{O}_{S}\left(K+C_{1}+C_{2}\right) \cong f^{*} \mathcal{O}_{B}(K)
$$

In order to see (3) we may restrict our attention to a local chart on $B$. Thus $S$ is of the form $\mathbb{P}^{1} \times B$. Let $(s: t)$ be coordinates on $\mathbb{P}^{1}$ and let $C_{1}=(s=0)$ and $C_{2}=(t=0)$. Let $z$ be a parameter on $B$ and let $g(z) d z$ be a 1 -form. Under the isomorphism $\psi$ we obtain

$$
\psi^{*}(g(z) d z)=\lambda \frac{d s}{s} \wedge g(z) d z
$$

where $\lambda$ is an unknown constant. Thus $\psi_{1}$ is given by

$$
\psi_{1}(g(z) d z)=\lambda g\left(f_{1}^{*}(z)\right) d\left(f_{1}^{*}(z)\right)
$$

Changing from $s$ to $t$ we obtain

$$
\psi^{*}(g(z) d z)=-\lambda \frac{d t}{t} \wedge g(z) d z
$$

hence

$$
\psi_{2}(g(z) d z)=-\lambda g\left(f_{2}^{*}(z)\right) d\left(f_{2}^{*}(z)\right)
$$

This proves (3).

### 12.4 Abundance

In this section we present a proof of (12.1.1).
Let $f: T \rightarrow S$ be a minimal semiresolution. By (12.2.8.1) there is a boundary $\Delta_{T}$ on $T$ such that $\left(T, \Delta_{T}\right)$ is $\log$ canonical and $K+\Delta_{T}=f^{*}(K+$ $\Delta)$. Thus abundance for $(S, \Delta)$ is equivalent to abundance for $\left(T, \Delta_{T}\right)$. In several instances it will be convenient to consider only the case when our surface $S$ is already semismooth.
12.4.1 Claim. (12.1.1) is true if $\nu=0$ and we are in case (1) of (12.3.3).

Proof. We may assume $S$ is semismooth. Choose $m$ such that $m\left(K+\Theta_{i}\right)$ is a linearly trivial Cartier divisor for every $i$. We claim that $12 m(K+\Delta) \sim 0$.

In order to see this we have to choose sections $\sigma_{i} \in \mathcal{O}_{S_{i}}\left(12 m\left(K+\Theta_{i}\right)\right)$ such that they patch together along the double curves. By assumption $\left\llcorner\Theta_{i}\right\lrcorner$ is connected and $K+\Theta_{i}$ is numerically trivial; thus

$$
H^{0}\left(\left\llcorner\Theta_{i}\right\lrcorner, \mathcal{O}_{\left\llcorner\Theta_{i}\right\lrcorner}\left(12 m\left(K+\operatorname{Diff}\left(\Theta_{i}-\left\llcorner\Theta_{i}\right\lrcorner\right)\right)\right)\right)
$$

is one dimensional, and it contains a unique normalized section $\rho_{i}$. Choose $\sigma_{i}$ such that it restricts to $\rho_{i}$. If $C \subset\left\llcorner\Theta_{i}\right\lrcorner$ is a proper subcurve then $\rho_{i} \mid C$ is the unique normalized section of $\mathcal{O}_{C}\left(12 m\left(K+\operatorname{Diff}\left(\Theta_{i}-\left\llcorner\Theta_{i}\right\lrcorner\right)\right) \mid C\right)$. Thus the $\sigma_{i}$ automatically patch together to a global section $\sigma \in H^{0}\left(S, \mathcal{O}\left(12 m\left(K_{S}+\right.\right.\right.$ $\Delta)$ )).
12.4.2 Claim. (12.1.1) is true in the following cases:
(1) $\nu=0$ in case (2) of (12.3.3); and
(2) $\nu=1$ provided $\nu\left(S_{i}, \Theta_{i}\right)=1$ for every irreducible component $S_{i}$ of $S^{\nu}$ and $S_{i} \cap S_{j}$ has no vertical components for $i \neq j$.

Proof. Let $\mu: S^{\mu} \rightarrow S$ be the normalization and let $D_{i} \subset S_{i}$ be the inverse images of the double curves. By assumption $D_{i}$ has one or two irreducible components. Moreover, except when $D_{i}$ is irreducible, it makes sense to talk about horizontal and vertical components of $\Theta_{i}$. If $\nu=0$ then (12.3.1.3) provides a morphism onto a curve, in the second case the morphism is given by abundance for $\left(S_{i}, \Theta_{i}\right)$.

By suitable indexing of the components $S_{i}(1 \leq i \leq n)$ of $S^{\mu}$ we may assume the following conditions

$$
\begin{aligned}
& \left\llcorner\Theta_{i\lrcorner}\right\lrcorner=D_{i}^{-} \cup D_{i}^{+} \cup(\text { vertical parts }) \quad\left(D_{1}^{-} \text {or } D_{n}^{+} \text {may be empty }\right) ; \text { and } \\
& D_{i}^{+} \cong \mu\left(D_{i}^{+}\right)=\mu\left(D_{i+1}^{-}\right) \cong D_{i+1}^{-} \quad \text { for } 1 \leq i \leq n-1
\end{aligned}
$$

We distinguish two cases according to the behaviour of $\mu$ on the curves $D_{1}^{-}$ and $D_{n}^{+}$.
(chain) $D_{1}^{-} \rightarrow \mu\left(D_{1}^{-}\right)$and $D_{n}^{+} \rightarrow \mu\left(D_{n}^{+}\right)$are isomorphisms and $\mu\left(D_{1}^{-}\right) \neq$ $\mu\left(D_{n}^{+}\right)$. If $D_{1}^{-} \rightarrow \mu\left(D_{1}^{-}\right)$or $D_{n}^{+} \rightarrow \mu\left(D_{n}^{+}\right)$is two-to-one, let $\tau_{1}$ (resp. $\tau_{n}$ ) denote the corresponding involution of $D_{1}^{-}$(resp. $D_{n}^{+}$). Otherwise let $\tau_{1}$ and $\tau_{n}$ be the identity.
(cycle) $D_{n}^{+} \cong \mu\left(D_{n}^{+}\right)=\mu\left(D_{1}^{-}\right) \cong D_{1}^{-}$.
The following obvious proposition describes $H^{0}(S, \mathcal{O}(m K+m \Delta))$ in terms of $S^{\mu}$ :
12.4.3 Proposition. Suppose that $m$ is sufficiently divisible. Set

$$
\begin{align*}
H(i) & =H^{0}\left(S_{i}, \mathcal{O}\left(m K+m \Theta_{i}\right)\right) \\
H\left(i^{-}\right) & =H^{0}\left(D_{i}^{-}, \mathcal{O}\left(m K+m \operatorname{Diff}\left(\Theta_{i}-D_{i}^{-}\right)\right)\right.  \tag{12.4.3.1}\\
H\left(i^{+}\right) & =H^{0}\left(D_{i}^{+}, \mathcal{O}\left(m K+m \operatorname{Diff}\left(\Theta_{i}-D_{i}^{+}\right)\right)\right.
\end{align*}
$$

and let

$$
\begin{align*}
\psi_{i}^{-} & : H(i) \rightarrow H\left(i^{-}\right) \\
\psi_{i}^{+} & : H(i) \rightarrow H\left(i^{+}\right)  \tag{12.4.3.2}\\
\phi_{i} & : H\left(i^{+}\right) \rightarrow H\left((i+1)^{-}\right) \\
\phi_{n} & : H\left(n^{+}\right) \rightarrow H\left(0^{-}\right) \quad(\text { for cycle only })
\end{align*}
$$

be the natural isomorphisms.
Then the sections of $H^{0}(S, \mathcal{O}(m K+m \Delta))$ are exactly those sequences $\left\{\eta_{i} \in H(i)\right\}$ which satisfy the following assumptions:
(chain) $\psi_{i+1}^{-}\left(\eta_{i+1}\right)=\phi_{i}\left(\psi_{i}^{+}\left(\eta_{i}\right)\right), \phi_{1}^{-}\left(\eta_{1}\right)$ is $\tau_{1}$-invariant and $\phi_{n}^{+}\left(\eta_{n}\right)$ is $\tau_{n}$ invariant.
(cycle) $\psi_{i+1}^{-}\left(\eta_{i+1}\right)=\phi_{i}\left(\psi_{i}^{+}\left(\eta_{i}\right)\right)$ and $\psi_{1}^{-}\left(\eta_{1}\right)=\phi_{n}\left(\psi_{n}^{+}\left(\eta_{n}\right)\right)$.
The choice of $\eta_{1}$ and the compatibility conditions $\psi_{i+1}^{-}\left(\eta_{i+1}\right)=\phi_{i}\left(\psi_{i}^{+}\left(\eta_{i}\right)\right)$ automatically determine the other $\eta_{i}$ uniquely. Let $\eta$ denote any set $\left\{\eta_{i}\right\}$ which satisfy these compatibility conditions.

We also need the following:
12.4.4 Lemma. The image $G$ of $\operatorname{Aut}\left(D_{1}^{-}, \operatorname{Diff}\left(\Theta_{1}-D_{1}^{-}\right)\right)$in $H\left(1^{-}\right)$is finite.

Proof. This is clear unless $D_{1}^{-} \cong \mathbb{P}^{1}$. If this holds then $\operatorname{Diff}\left(\Theta_{1}-D_{1}^{-}\right)$is klt in case $\nu=0$ and has degree $>2$ in case $\nu=1$. Thus Supp $\operatorname{Diff}\left(\Theta_{1}-D_{1}^{-}\right)$ consists of $\geq 3$ points, hence $\operatorname{Aut}\left(D_{1}^{-}, \operatorname{Diff}\left(\Theta_{1}-D_{1}^{-}\right)\right)$is itself finite.
12.4.5 Corollary. Notation as above. Let $G=\left\{g_{1}, \ldots, g_{k}\right\}$. Then

$$
\left(g_{1}^{*}(\eta) \otimes g_{2}^{*}(\eta) \otimes \cdots \otimes g_{k}^{*}(\eta)\right)^{\otimes 2}
$$

descends to a section of

$$
\mathcal{O}_{S}(2 k m K+2 k m \Delta) .
$$

Proof. Note first that by (12.3.4) all the pairs ( $\left.D_{i}^{-}, \operatorname{Diff}\left(\Theta_{i}-D_{i}^{-}\right)\right)$and $\left(D_{i}^{+}, \operatorname{Diff}\left(\Theta_{i}-D_{i}^{+}\right)\right)$are isomorphic, and thus all the corresponding groups are the same. Furthermore, any isomorphism obtained by a combination of the isomorphisms in (12.4.3.2) is, up to a sign, induced by an isomorphism of the underlying pairs. Therefore, the second set of compatibility conditions are satisfied for $\eta$ up to an element of $G$ and up to a sign.

Therefore, in the cycle case, there is an element $g \in G$ such that

$$
\psi_{1}^{-}\left(\eta_{1}\right)= \pm g^{*}\left(\phi_{n}\left(\psi_{n}^{+}\left(\eta_{n}\right)\right)\right),
$$

and similarly for chains. By taking the product over all $g_{i} \in G$ and taking the square we get rid of the ambiguities.
12.4.6 Claim. (12.1.1) is true if $\nu=1$.

Proof. Let $(S, \Delta)$ be slc with $\nu=1$. As we remarked earlier, it is sufficient to consider the case when $S$ is semismooth, and hence $D$ is smooth. Let $D=D_{0} \cup D_{1}$, where $D_{0}$ is the union of those irreducible components $D^{j}$ such
that $\nu\left(D^{j}, K_{S}+\Delta\right)=0$ and at least one of the irreducible components $S_{i}$ containing $D^{j}$ has $\nu=1$.

Let $\pi: S^{\prime} \rightarrow S$ be the morphism obtained by normalizing in a neighborhood of $D_{0}$. The connected components of ( $S^{\prime}, \Theta^{\prime}$ ) have either $\nu=0$ or $\nu=1$ and they satisfy the assumptions of (12.4.2.2). Thus abundance holds for $\left(S^{\prime}, \Theta^{\prime}\right)$. We need to analyze the patching of sections along $\pi^{-1}\left(D_{0}\right)$.
12.4.7 Lemma. Assume that $(S, \Delta)$ satisfies the assumptions of (12.4.2.2). Let $p: S \rightarrow B$ be the morphism given by a large multiple of $K+\Delta$. Let $\Delta^{\prime}$ be the vertical part of $\Delta$. Then $\left\llcorner\Delta^{\prime}\right\lrcorner$ is the union of fibers of $p$. In particular for every irreducible $C \subset\left\llcorner\Delta^{\prime}\right\lrcorner$ the restriction ( $C$, Diff $_{C}(\Delta-C)$ ) is either not klt or $C$ is a smooth elliptic curve and Diff $_{C}(\Delta-C)=0$. Furthermore, there are sections

$$
\tau \in H^{0}\left(S, \mathcal{O}_{S}(2 m K+2 m \Delta)\right)
$$

whose restriction to $\left\llcorner\Delta^{\prime}\right\lrcorner$ is the unique normalized section of

$$
\mathcal{O}_{\left\llcorner\Delta^{\prime}\right\lrcorner}\left(2 m(K+\Delta) \mid\left\llcorner\Delta^{\prime}\right\lrcorner\right) .
$$

These sections have no common zeros.
Proof. The first claim follows from (12.3.2) applied to the normalization of $S$. Let $b_{i} \in B$ be the points corresponding to $\llcorner\Delta\lrcorner$. For some $m>1$ we have

$$
\mathcal{O}_{S}(m K+m \Delta)=p^{*}\left(\mathcal{O}_{B}\left(m K+m \sum\left[b_{i}\right]+m P\right)\right)
$$

for some $\mathbb{Q}$-divisor $P$. Since $K_{B}+\sum\left[b_{i}\right]+P$ is ample, for $m \gg 1$, it follows that there are sections of $\mathcal{O}_{B}\left(m K+m \sum\left[b_{i}\right]+m P\right)$ taking any preassigned value at the points $b_{i}$. Furthermore these sections will not have any common zeros.
12.4.7.1 Complement. It is easy to see that (12.4.7) also holds if $(S, \Delta)$ is a semi-smooth surface, $B$ is an affine curve and $p: S \rightarrow B$ is a proper and flat morphism such that $K+\Delta$ is $p$-trivial and every double curve of $S$ is horizontal.

Now we can finish the proof of (12.4.6). By (12.4.7) and (12.4.1) we can choose sections of $\mathcal{O}_{S^{\prime}}\left(2 m K+2 m \Theta^{\prime}\right)$ which induce the unique normalized section of

$$
\mathcal{O}\left(2 m K_{S^{\prime}}+2 m \Theta^{\prime} \mid \pi^{-1}\left(D_{0}\right)\right) .
$$

These sections will descend to $S$ and they have no common zeros.

### 12.5 Hodge Theory

In this section we prove (12.1.2). The following lemma is useful in comparing the cohomology of $S$, with that of a partial resolution of $S$.
12.5.1 Lemma. Consider the following commutative diagram of Abelian groups

If the rows are exact, $\alpha$ and $\beta$ are surjective, and

$$
\begin{equation*}
d^{\prime}(\operatorname{ker} \beta)=\operatorname{im} d^{\prime} \cap \operatorname{ker} \gamma \tag{12.5.1.1}
\end{equation*}
$$

then $\omega$ is surjective. (The last condition holds for example if there are compatible splittings $\beta^{\prime}$ and $\gamma^{\prime}$ of the maps $\beta$ and $\gamma$, or if $\gamma$ is an isomorphism.)

Proof. An easy diagram chase, left to the reader.
We first prove (12.1.2) assuming that $S$ is semismooth.
12.5.2 Lemma. If $S$ is semismooth then the natural map

$$
i_{p}: H^{p}(S, \mathbb{C}) \longrightarrow H^{p}\left(S, \mathcal{O}_{S}\right) \quad \text { is surjective for every } p
$$

Proof. Let $g: S^{\mu} \longrightarrow S$ be the normalization of $S ; S^{\mu}$ is smooth. We compare the cohomology of $S$ and $S^{\mu}$. There are two relevant exact sequences:

$$
\begin{align*}
& 0 \longrightarrow \mathbb{C}_{S} \longrightarrow g_{*} \mathbb{C}_{S^{\mu}} \longrightarrow \mathcal{G} \longrightarrow 0  \tag{12.5.3}\\
& 0 \longrightarrow \mathcal{O}_{S} \longrightarrow g_{*} \mathcal{O}_{S^{\mu}} \longrightarrow \mathcal{F} \longrightarrow 0 \tag{12.5.4}
\end{align*}
$$

We identify the sheaves $\mathcal{F}$ and $\mathcal{G}$, which are defined at the moment as cokernels in (12.5.3-4).
$D_{\mu}$ is smooth and maps two-to-one to $D=D_{S}$. Let $\tau$ be the natural involution on $D_{\mu}$. The involution $\tau$ acts naturally on the sheaves $g_{*}\left(\mathcal{O}_{D_{\mu}}\right)$ and $g_{*}\left(\mathbb{C}_{D_{\mu}}\right)$. Under this action, these sheaves decompose into invariant and anti-invariant parts; the sheaves $\mathcal{F}$ and $\mathcal{G}$ are then the anti-invariant parts. Let $P$ be the union of all the pinch points and let $L^{2} \cong \mathcal{O}(P)$ the line bundle defining the double cover. It is an easy computation to check that $\mathcal{F}=L^{-1}$.

Now we compare the two long exact sequences of (12.5.3) and (12.5.4): (12.5.5)

$$
\begin{array}{ccccc}
H^{p-1}(D, \mathcal{G}) \longrightarrow H^{p}(S, \mathbb{C}) & H^{p}\left(S^{\mu}, \mathbb{C}\right) & \xrightarrow{c_{p}} H^{p}(D, \mathcal{G}) \\
k_{p-1} \downarrow \\
i_{p} \downarrow & j_{p} \downarrow & \\
H^{p-1}(D, \mathcal{F}) \longrightarrow H^{p}\left(S, \mathcal{O}_{S}\right) \longrightarrow H^{p}\left(S^{\mu}, \mathcal{O}_{S^{\mu}}\right) \xrightarrow{d_{p}} \xrightarrow{ } \longrightarrow H^{p}(D, \mathcal{F}) .
\end{array}
$$

Here the diagram commutes, and the horizontal sequences are exact. As previously observed, since $S^{\mu}$ is smooth the map $j_{p}$ is surjective.

Now we have to find compatible splittings of the maps $j_{p}$ and $k_{p}$; these are given by Hodge theory. In fact the cohomology groups $H^{p}\left(D_{\mu}, \mathbb{C}\right)$ decompose into invariant and anti-invariant subspaces under the action of $\tau$ and $H^{p}(D, \mathcal{G})$ is just the anti-invariant part. As such $H^{p}(D, \mathcal{G})$ inherits a filtration from the natural Hodge filtration on $H^{p}\left(D_{\mu}, \mathbb{C}\right)$. Now consider the commutative square

Clearly the maps $e_{p}$ and $f_{p}$ preserve the Hodge filtrations. But the horizontal maps $c_{p}$ and $d_{p}$ of (12.5.5) factor through the horizontal maps $e_{p}$ and $f_{p}$ of (12.5.6). Thus there is a natural splitting of the map $k_{p}$, compatible with the splitting of $j_{p}$. Now apply (12.5.1) to deduce $i_{p}$ is surjective.

We are now in a position to prove (12.1.2).
Proof. Let $f: T \longrightarrow S$ be a semiresolution of $S$. By (12.5.2), the natural maps

$$
j_{p}: H^{p}(T, \mathbb{C}) \longrightarrow H^{p}\left(T, \mathcal{O}_{T}\right)
$$

are surjective.
We wish to compare the cohomology of $T$ and $S$. There are two relevant spectral sequences; the Leray-Serre spectral sequences associated to the map $f$ and the sheaves $\mathbb{C}_{T}, \mathcal{O}_{T}$. The respective $E_{2}$ terms of the two spectral sequences are $H^{p}\left(S, R^{q} f_{*} \mathbb{C}_{T}\right)$ and $H^{p}\left(S, R^{q} f_{*} \mathcal{O}_{T}\right)$. Both spectral sequences degenerate at the $E_{3}$ level, and converge to $H^{*}(T, \mathbb{C})$ and $H^{*}\left(T, \mathcal{O}_{T}\right)$ respectively.

Let $F$ be the exceptional locus of the map $f$. As $F$ is one dimensional, the only interesting cohomology groups to identify at the $E_{2}$ level are

$$
H^{0}\left(S, R^{1} f_{*} \mathbb{C}_{T}\right)=H^{1}\left(F, \mathbb{C}_{F}\right) \quad \text { and } \quad H^{0}\left(S, R^{1} f_{*} \mathcal{O}_{T}\right)=H^{1}\left(F, \mathcal{O}_{F}\right)
$$

The first identification is easy; given any open neighbourhood of $F$, we can always find a smaller one which retracts to $F$. For the second we use (12.2.8). In fact if we push down the short exact sequence

$$
0 \longrightarrow \mathcal{O}_{T}(-F) \longrightarrow \mathcal{O}_{T} \longrightarrow \mathcal{O}_{F} \longrightarrow 0
$$

by $f$, we obtain a sequence

$$
0 \longrightarrow R^{1} f_{*} \mathcal{O}_{T}(-F) \longrightarrow R^{1} f_{*} \mathcal{O}_{T} \longrightarrow R^{1} f_{*} \mathcal{O}_{F}=H^{1}\left(F, \mathcal{O}_{F}\right) \longrightarrow 0 .
$$

The two spectral sequences give rise to the following commutative diagram of cohomology groups, with exact rows:

We apply (12.5.1). We need to find a compatible splitting for $k_{1}$. Let $F_{j}$ be the connected compnents of $F$. By (12.2.8) these come in three types. If $F_{j}$ is a tree of rational curves then $H^{1}\left(F_{j}, \mathbb{C}\right)=0$. If $F_{j}$ is a cycle of rational curves then $H^{1}\left(F_{j}, \mathbb{C}\right) \rightarrow H^{1}\left(F, \mathcal{O}_{F}\right)$ is an isomorphism. Finally if $F_{j}$ is a smooth elliptic curve then $H^{1}\left(T, \mathbb{C}_{T}\right) \rightarrow H^{1}\left(F, \mathbb{C}_{F}\right)$ factors through $H^{1}\left(S^{\mu}, \mathbb{C}\right)$ hence the splitting of $k_{1} \mid F_{j}$ provided by Hodge decomposition works.
$i_{0}$ is automatically surjective, and there is a similar commutative diagram

(12.5.1.1) is vacuously satisfied, hence $i_{2}$ is surjective.
12.5.8 Remark. One can see that the kernel of $i_{p}$ in (12.1.2) is precisely $F^{1} H^{p}\left(S, \mathbb{C}_{S}\right)$ (given by the natural mixed Hodge structure, cf. [GriffithsSchmid73]). The proof given above could have been shortened by using more difficult Hodge theoretic methods.

# 13. ABUNDANCE FOR THREEFOLDS, 

$$
\text { CASE } \nu(X)=1
$$

János Kollár, Kenji Matsuki, and James MCKernan

This chapter treats the proof of the following result, proved in [Miyaoka88b] (see (11.1.2) for definitions):
13.1 Theorem. Let $X$ be a minimal threefold. If the numerical dimension $\nu(X)$ is one, then $\left|m K_{X}\right|$ is base point free for some $m>0$.

The main steps in the proof are almost identical to those of Chapter 11, but of course some steps are harder. Here is a generalization of (11.3.2) to dimension three.
13.2 Lemma. Let $(X, \Delta)$ be a $\mathbb{Q}$-factorial klt pair (2.13.5), $\operatorname{dim} X=3$. Suppose there is a nef divisor $D \in\left|m\left(K_{X}+\Delta\right)\right|$ such that $X \backslash D$ has terminal singularities. Let $B=D_{\text {red }}$. Then there is a threefold $\hat{X}$, with boundary $\hat{\Delta}+\hat{B}$, where $\hat{B}$ is reduced, such that:
(1) The pair $(\hat{X}, \hat{\Delta}+\hat{B})$ has $\mathbb{Q}$-factorial log canonical singularities, $\hat{X} \backslash \hat{B}$ is isomorphic to $X \backslash B$ and there is a divisor $\hat{D} \in\left|m\left(K_{\hat{X}}+\hat{\Delta}+\hat{B}\right)\right|$. Moreover $\hat{D}_{\text {red }}=\hat{B}$.
(2) $K_{\hat{X}}+\hat{\Delta}+\hat{B}$ is nef.
(3) $\nu\left(X, K_{X}+\Delta\right)=\nu\left(\hat{X}, K_{\hat{X}}+\hat{\Delta}+\hat{B}\right)$ and $\kappa\left(X, K_{X}+\Delta\right)=\kappa\left(\hat{X}, K_{\hat{X}}+\right.$ $\hat{\Delta}+\hat{B})$.

Proof. By (6.16.1) or (20.9) there is a projective partial resolution of singularities $\mu: X_{0} \rightarrow X$ such that
(1) the divisor $B_{0}=\left(\mu^{*} B\right)_{\text {red }}$ is a normal crossing divisor,
(2) $\mu:\left(X_{0} \backslash B_{0}\right) \rightarrow(X \backslash B)$ is an isomorphism.

As $(X, \Delta)$ has klt singularities, $m\left(K_{X_{0}}+\mu_{*}^{-1} \Delta+E\right)=\mu^{*} D+\Gamma=\tilde{D}$, where $E$ is the union of the $\mu$-exceptional divisors and $\Gamma$ is effective and supported on the exceptional locus. In particular, $\operatorname{Supp} \tilde{D}=\operatorname{Supp} \mu^{*} D$. Now we replace
$\mu_{*}^{-1} \Delta$ with $\Delta_{0}$ where we only include those components of $\mu_{*}^{-1} \Delta$ which are not components of $B_{0}$. With this choice of $\Delta_{0}, \Delta_{0}+B_{0}$ is a boundary, and there is a divisor $D_{0} \in\left|m\left(K_{X_{0}}+\Delta_{0}+B_{0}\right)\right|$

We now apply the log minimal model program to ( $X_{0}, \Delta_{0}+B_{0}$ ). We construct $X_{i}, \Delta_{i}, B_{i}$ and $D_{i}$ satisfying (1) inductively. If $K_{X_{i}}+\Delta_{i}+B_{i}$ is not nef, there exists an elementary contraction $\phi_{i}: X_{i} \rightarrow Z_{i}[K M M 87,4-2-1$ and $3-2-1]$ associated to a $\log$ extremal ray with respect to $K_{X_{i}}+\Delta_{i}+B_{i}$. Clearly the map $\phi_{i}$ is birational.

If $\phi_{i}$ is a divisorial contraction, we set $X_{i+1}=Z_{i}, \Delta_{i+1}=\phi_{i *}\left(\Delta_{i}\right), B_{i+1}=$ $\phi_{i *} B_{i}$ and $D_{i}=\phi_{i_{*}} D_{i}$. (By [KMM87, 5-1-6], the image ( $X_{i+1}, \Delta_{i+1}+B_{i+1}$ ) is $\mathbb{Q}$-factorial $\log$ terminal, and (13.2.4) implies that $B_{i+1}$ and $D_{i+1}$ are divisors.)

Otherwise there is a log flip, i.e., a small birational morphism $\phi_{i}^{+}: X_{i+1} \rightarrow$ $Z_{i}$. We take $\Delta_{i+1}, B_{i+1}$ and $D_{i+1}$ to be the birational transforms of $B_{i}$ and $D_{i}$ under $\phi_{i}$. (By [KMM87, 5-1-11] the $\log \operatorname{flip}\left(X_{i+1}, \Delta_{i+1}+B_{i+1}\right)$ is $\log$ canonical and $\mathbb{Q}$-factorial in a neighborhood of $B_{i+1}$. The pluricanonical class pushes across the flip, because it may be defined using differential forms on a complement of any codimension 2 locus.)
$K_{X_{i}}+\Delta_{i}+B_{i}$ is negative relative to the morphism $\phi_{i}$. Since $D_{i} \in$ $\left|m\left(K_{X_{i}}+\Delta_{i}+B_{i}\right)\right|$ is supported on $B_{i}$, the exceptional locus of $\phi_{i}$ is contained in $B_{i}$. By (7.1) the process we have just described must terminate at some $i$, and we set $\hat{X}=X_{i}, \hat{\Delta}=\Delta_{i}, \hat{B}=B_{i}$ and $\hat{D}=D_{i}$.

Conditions (1) and (2) are automatic from the construction. (3) follows from (11.3.3) and (13.2.4) applied to the pullbacks of the divisors $m\left(K_{X}+\Delta\right)$ and $D_{i}$ to a common resolution.
13.2.4 Lemma. The set theoretic image of an effective nef divisor under a birational morphism is divisorial.

Proof. Let $f: X \rightarrow Y$ be a birational morphism, and let $L$ be an effective nef $\mathbb{Q}$-Cartier divisor on $X$. We may assume that $L$ is Cartier. Let $M=f_{*} L$ be the cycle theoretic push forward, and let $M_{0}=f(\operatorname{Supp} L)$ be the set theoretic image. Write $M_{0}-\operatorname{Supp} M=C_{0} \cup \ldots \cup C_{i}$ where $C_{i}$ are distinct irreducible components. By taking generic hyperplane sections of $Y$, we may assume that $\min \left\{\operatorname{dim} C_{i}\right\}=0$. Using generic hyperplane sections on $X$ we may assume $\operatorname{dim} X=2$. Choosing a resolution of singularities for $X$ and pulling back $L$, we may assume that $X$ is smooth. But by the Hodge index theorem the intersection matrix of divisors supported on the exceptional locus of $f$ over $C_{i}$ is negative definite, and $L$ is supported on this locus near $C_{i}$, a contradiction.

### 13.3 Conclusion of Proof of (13.1).

Let $X$ be a minimal threefold, i.e. a threefold with $\mathbb{Q}$-factorial terminal singularities such that $K_{X}$ is nef. Suppose that $D \in\left|m K_{X}\right|$ (9.0.6) and let
$B=D_{\text {red }}$.
13.3.1 Lemma. There is a threefold $\hat{X}$, birational to $X$, with reduced boundary $\hat{B}$ such that:
(1) The pair $(\hat{X}, \hat{B})$ is $\mathbb{Q}$-factorial and $\log$ canonical, $\hat{X} \backslash \hat{B}$ has terminal singularities, and there is a divisor $\hat{D} \in\left|m K_{\hat{X}}\right|$. Moreover $\hat{D}_{\text {red }}=\hat{B}$.
(2) $K_{\hat{X}}+\hat{B}$ is nef.
(3) $\nu(X)=\nu\left(\hat{X}, K_{\hat{X}}+\hat{B}\right)$ and $\kappa(X)=\kappa\left(\hat{X}, K_{\hat{X}}+\hat{B}\right)$.

Proof. This is an immediate consequence of (13.2.1).
13.3.2 Lemma. There is a threefold $X^{\prime}$, birational to $X$, with a reduced boundary $B^{\prime}$ satisfying conditions (1-3) of (13.2.1) and
(4) every connected component of $B^{\prime}$ is irreducible.

Proof. It remains to modify $\hat{X}$ further to achieve (4). Suppose $S$ is a prime component of $\hat{B}$ which is not isolated in $\hat{B}$. We will apply the log minimal model program to $K_{\hat{X}}+\hat{B}-S$.

Suppose we have constructed a sequence of pairs $\left(X_{j}, B_{j}\right)\left(\left(X_{0}, B_{0}\right)=\right.$ $(\hat{X}, \hat{B})$ ) and birational morphisms $\phi_{j}: X_{j} \rightarrow X_{j+1}$, with respect to $K_{X_{j}}+$ $B_{j}-S_{j}$ for $j \leq i-1$, where $B_{j+1}$ and $S_{j+1}$ are respectively either $\phi_{j_{*}}\left(B_{j}\right)$ and $\phi_{j_{*}}\left(S_{j}\right)$, if $\phi_{j}$ is a divisorial contraction, or the birational transforms of $B_{j}$ and $S_{j}$ under $\phi_{j}$, if $\phi_{j}$ is a $\log$ flip. As in (13.2.1), $\left(X_{j}, B_{j}\right)$ satisfies properties (1-3).

Suppose $S_{i}$ is still not isolated in $B_{i}$. Then there is another component $S^{\prime}$ of $B_{i}$ which meets $S_{i}$ in a curve $C$ (recall $X_{i}$ is $\mathbb{Q}$-factorial). Let $H$ be an ample divisor and set $C^{\prime}=H \cap S^{\prime}$. Let $L_{i}$ be the line bundle $\mathcal{O}_{X_{i}}\left(m\left(K_{X_{i}}+B_{i}\right)\right)$. It is automatic that $\nu\left(S,\left.L_{i}\right|_{S}\right)=0$ and so $\left.\operatorname{deg} L_{i}\right|_{C^{\prime}}=0$, as the curve $C^{\prime}$ lies in $S^{\prime}$. On the other hand, as $H$ is ample, $S \cdot C^{\prime}=H \cdot C>0$, and so

$$
\left(K_{X_{i}}+B_{i}-S_{i}\right) \cdot C^{\prime}<0 .
$$

As $L_{i}$ is nef, the Theorem on the Cone [KMM87, 4.2.1] implies there is a log extremal ray $R$ such that

$$
\left(K_{X_{i}}+B_{i}-S_{i}\right) \cdot R<0
$$

with $L \cdot R=0$. Now $S \cdot R>0$ and the support of the base locus of $K_{X_{i}}$ is a subset of $\operatorname{supp}\left(B_{i}\right)$ and so $R \subset \operatorname{supp}\left(B_{i}-S\right)$. By (8.1), there is a $\log$ flip of $R$ with respect to $L$ and by (7.1) this sequence of $\log$ flips terminates. Thus at some stage $S_{i}$ is isolated in $B_{i}$.

However if $T$ is another prime component of $B^{\prime}$ and $T$ is isolated in $B^{\prime}$, then $T_{i}$ (the component of $B_{i}$ corresponding to $T$ ) is isolated in $B_{i}$ (as each
$\phi_{j}$ only modifies points of $\left.S_{j}\right)$. In this way we isolate every component of $B^{\prime}$, one by one.

Proof of (13.1.1). Pick a component $S$ of $B^{\prime}$, and put $\Delta=\operatorname{Diff}_{S}(0)$. By (16.9.1), the pair $(S, \Delta)$ is semi log canonical and so (12.1.1) implies $K_{S}+\Delta$ is torsion. Just as before, by (11.3.6), we may find a finite Galois cover $\pi: \tilde{U} \longrightarrow U_{1}$, étale in codimension one, such that

$$
\tilde{S} \sim m^{\prime} \tilde{G}, \quad K_{\tilde{U}}+\tilde{S} \sim d^{\prime} \tilde{G}, \quad \text { and } \quad \omega_{\tilde{S}}=\left.\mathcal{O}_{\tilde{U}}(\tilde{S})\right|_{\tilde{S}}=\mathcal{O}_{\tilde{S}}
$$

where $\tilde{S}=\pi^{*} S$. Now if we can apply (11.3.7), then we may conclude just as in Chapter 11. Conditions (1) and (2) of (11.3.7) are automatic.

Consider the commutative square

where $\tilde{S}_{n}$ is defined as in Chapter 11. As the first vertical map is an isomorphism (the support of $\tilde{S}$ and $\tilde{S}_{n}$ are the same), and the map $i_{p}$ is surjective (this is (12.1.2)), the map $\rho$ is surjective as well, which is condition (3) of (11.3.7).

# 14. ABUNDANCE FOR THREEFOLDS, 

$$
\nu(X)=2 \operatorname{IMPLIES} \quad \kappa(X) \geq 1
$$

## Dan Abramovich, Lung-Ying Fong, and Kenji Matsuki

We continue our treatment of Miyaoka's and Kawamata's proof of the abundance conjecture for threefolds. In this chapter, we look at the case $\nu(X)=2$. The method we use in sections (14.3-4) is due to Kollár.

### 14.1 A special case

Let us first consider the following very special case, which gives some idea about the line of proof in the general case.

Assume $X$ is a smooth minimal model with $\nu(X)=2$, and assume the existence of a smooth member $D \in\left|m K_{X}\right|$. As $\nu\left(D, K_{D}\right)=1$, by abundance for surfaces (11.3.1), $\kappa(D)=1$ and $D$ is an elliptic surface over some curve.

Let $H$ be a hyperplane section of $X$. Kodaira vanishing on $H$ gives

$$
H^{i}\left(X, m K_{X}+l H\right) \simeq H^{i}\left(X, m K_{X}+(l+1) H\right)
$$

for $i \geq 2, m>1$ and $l \geq 0$. But since $H$ is ample, this group vanishes for large $l$. Therefore we get

$$
H^{i}\left(X, m K_{X}\right)=0 \quad \text { for } \quad i \geq 2
$$

We now use Riemann-Roch. Since $K_{X}^{3}=0$, the coefficient of the leading (linear) term in $\chi\left(n K_{X}\right)$ is $K \cdot c_{2}(X)$, which is proportional to $c_{2}(D)$, which is nonnegative [BPV84, p. 188]. Hence $\chi\left(n K_{X}\right) \geq C$ for some constant $C$, and $h^{0}\left(X, n K_{X}\right) \geq C+h^{1}\left(X, n K_{X}\right)$. From the exact sequence

$$
0 \rightarrow \mathcal{O}_{X}\left((n-m) K_{X}\right) \rightarrow \mathcal{O}_{X}\left(n K_{X}\right) \rightarrow \mathcal{O}_{D}\left(\left.n K_{X}\right|_{D}\right) \rightarrow 0
$$

we get $h^{2}\left(D,\left.n K_{X}\right|_{D}\right)=0$ and

$$
H^{1}\left(X, n K_{X}\right) \rightarrow H^{1}\left(D,\left.n K_{X}\right|_{D}\right) \rightarrow 0
$$

Riemann-Roch on $D$ implies that $\chi\left(D,\left.n K_{X}\right|_{D}\right)$ is constant. Since $\nu\left(\left.K_{X}\right|_{D}\right)=$ 1 , the abundance theorem on surfaces implies that both $h^{0}\left(D,\left.n K_{X}\right|_{D}\right)$ and $h^{1}\left(D,\left.n K_{X}\right|_{D}\right)$ grow with $n$. Hence $h^{1}\left(X, n K_{X}\right)$ grows with $n$. This proves that $\kappa(X)>0$.

We begin with a construction similar to that of (13.2).
14.2 Lemma. There is a normal threefold $X^{\prime}$, birational to $X$, with reduced boundary $B^{\prime}$, and such that
(1) $\left(X^{\prime}, B^{\prime}\right)$ has $\mathbb{Q}$-factorial log canonical singularities and $\left(X^{\prime}, 0\right)$ has only log terminal singularities. There exists a divisor $D^{\prime} \in\left|m K_{X^{\prime}}\right|$. Moreover $B^{\prime}=D_{\text {red }}^{\prime}$.
(2) $K_{X^{\prime}}+B^{\prime}$ is nef.
(3) $\nu(X)=\nu\left(X^{\prime}, K_{X^{\prime}}+B^{\prime}\right)$ and $\kappa(X)=\kappa\left(X^{\prime}, K_{X^{\prime}}+B^{\prime}\right)$.
(4) $L^{\prime}=m\left(K_{X^{\prime}}+B^{\prime}\right)$ is Cartier.
(5) If $C$ is a curve in $X^{\prime}$ with $C \cdot\left(K_{X^{\prime}}+B^{\prime}\right)=0$, then $C \cdot K_{X^{\prime}} \geq 0$. If $D$ is a curve in $X^{\prime}$ with $D \cdot\left(K_{X^{\prime}}+B^{\prime}\right)>0$, then $\left(X^{\prime}, B^{\prime}\right)$ is log terminal along the generic point of $D$.

Proof. As in (13.2), we can apply the log minimal model program to construct a threefold $\tilde{X}$, with boundary $\tilde{B}$ satisfying (1), (2) and (3).

Replacing $m$ by a multiple, we can assume that $L=m\left(K_{\tilde{X}}+\tilde{B}\right)$ is a Cartier divisor.

We construct $X^{\prime}$ inductively. Take $X_{0}^{\prime}=\tilde{X}, B_{0}^{\prime}=\tilde{B}$ and $D_{0}^{\prime}=\tilde{D}$. If there exists a curve $C$ in $X_{i}^{\prime}$ such that $C \cdot\left(K_{X_{i}^{\prime}}+B_{i}^{\prime}\right)=0$ and $C$. $K_{X_{i}^{\prime}}<0$, then there is some $K_{X_{i}^{\prime}}$ extremal ray $R_{i}$ lying on the hyperplane $\left\{\Gamma \mid \Gamma \cdot\left(K_{X_{i}^{\prime}}+B_{i}^{\prime}\right)=0\right\}$. We have a divisorial contraction or a $\log$ flip $\phi_{i}$ : $X_{i}^{\prime} \longrightarrow X_{i+1}^{\prime}$ associated with $R_{i}$. Put $B_{i+1}^{\prime}=\phi_{i *}\left(B_{i}^{\prime}\right)$ and $D_{i+1}^{\prime}=\phi_{i *}\left(D_{i}^{\prime}\right)$. Then (1-4) are clearly satisfied. Since $(\tilde{X}, 0)$ has log terminal singularities, this process will stop and gives $X^{\prime}$.

It remains to check inductively that if we contract a divisor by $\phi_{i}$, we still have log terminal singularities generically along curves having positive intersection with $K_{X_{i+1}^{\prime}}+B_{i+1}^{\prime}$. Since $\nu\left(B_{i}^{\prime},\left.L_{i}^{\prime}\right|_{B_{i}^{\prime}}\right)=1$, (12.1.1) implies that $\left|m^{\prime} L^{\prime}\right|_{B^{\prime}} \mid$ defines a morphism $f$ from $B_{i}^{\prime}$ to some curve. Let $S$ be a component of $B_{i}^{\prime}$ on which $L_{i}^{\prime}$ is not numerically trivial, and let $\lambda: S^{\lambda} \rightarrow S$ be the normalization. Consider the different $\Theta$ defined by $\lambda^{*}\left(K_{X_{i}^{\prime}}+B_{i}^{\prime}\right)=K_{S^{\lambda}}+\Theta$ (cf. (16.6)). $\Theta$ lies over the nonnormal locus of $B_{i}^{\prime}$ and the singular locus of $X_{i}^{\prime}$. Let $\Theta_{h}$ be the horizontal part of $\Theta$. If the generic fibre $F$ of $f \circ \lambda$ is a smooth elliptic curve, then $\Theta_{h}=0$. Otherwise $F \cong \mathbb{P}^{1}$, and $\Theta_{h} \cdot F=2$. Decompose $\Theta_{h}$ as $\sum c_{k} \Gamma_{k}+\sum d_{l} \Delta_{l}$ in a neighborhood of $F$, where the $\Gamma_{k}$ map under $\lambda$ to the singular locus of $X_{i}^{\prime}$ and the $\Delta_{l}$ to the nonnormal locus of $B_{i}^{\prime}$. Then

$$
\begin{equation*}
\sum c_{k}+\sum d_{l}=2 \tag{14.2.1}
\end{equation*}
$$

By the inductive assumption, ( $X_{i}^{\prime}, B_{i}^{\prime}$ ) has log terminal singularities along $\lambda\left(\Gamma_{k}\right)$ and $\lambda\left(\Delta_{l}\right)$. In particular, $X_{i}^{\prime}$ is smooth along $\lambda\left(\Delta_{l}\right)$ and $d_{l}=1$, while along $\lambda\left(\Gamma_{k}\right), X_{i}^{\prime}$ has index $m_{k}$ quotient singularities $\left(m_{k} \geq 2\right)$ and $c_{k}=1-\frac{1}{m_{k}}$
(See (16.6)). The set of solutions $\left(d_{1}, \cdots ; m_{1}, m_{2}, \cdots\right)$ of (14.2.1) can be easily enumerated:

Case 1 ( 1,$1 ;$ ),
Case $2(1 ; 2,2)$, and
Case 3 (;2,4,4), (;3,3,3), (;2,3,6), and (;2,2,2,2).
Suppose that $\phi_{i}$ contracts a $K_{X_{i}^{\prime}}$ extremal curve $C$ on $X_{i}^{\prime} . C \cdot D_{i}^{\prime}<0$ implies that $C \subset B_{i}^{\prime} . C \cdot\left(K_{X_{i}^{\prime}}+B_{i}^{\prime}\right)=0$, and hence $C$ is contained in a fibre of $f . C \cdot B_{i}^{\prime}>0$ implies that $C$ has to intersect a component of $B_{i}^{\prime}$ positively. We see at once that $\phi_{i}$ can never contract components that are in Case 3. In Case 1, $S$ intersects two other components $S_{1}$ and $S_{2}$ of $B_{i}^{\prime}$. $X_{i}^{\prime}$ is smooth in a neighborhood of $\lambda(F)$, hence $X_{i+1}^{\prime}$ is generically smooth along the intersection of $\phi_{i}\left(S_{1}\right)$ and $\phi_{i}\left(S_{2}\right)$. In Case 2, $X_{i}^{\prime}$ has only two curves of $A_{1}$-singularities in a neighborhood of $\lambda(F)$, hence it is canonical. Therefore $X_{i+1}^{\prime}$ has terminal singularities in a neighborhood of $\phi_{i}(\lambda(F))(2.28 .3)$, thus $X_{i+1}^{\prime}$ is generically smooth along $\phi_{i}(S)$. (In fact one can see that in this case $\lambda(F) \cdot K \geq 0$, and therefore we never have to contract $\lambda(F)$.)

### 14.3 Computing the second Todd class.

We now proceed with the proof of the abundance conjecture and establish an inequality involving the second Todd class on a resolution of $X^{\prime}$. This is used in the final step when we apply Riemann-Roch.
14.3.1 Lemma. $X^{\prime}, B^{\prime}$ and $L^{\prime}$ as in section 14.2. Let $\mu: V \rightarrow X^{\prime}$ be a resolution of singularities. Then we have

$$
\mu^{*} L^{\prime} \cdot\left(K_{V}^{2}+c_{2}(V)\right) \geq L^{\prime} \cdot\left(K_{X^{\prime}}^{2}+\hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\right)\right) .
$$

## Proof. Let

$$
\mu_{*}\left(K_{V}^{2}+c_{2}(V)\right)-\left(K_{X^{\prime}}^{2}+\hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\right)\right)=\sum a_{i} C_{i} .
$$

Then all the 1 -cycles $C_{i}$ are supported on the singular locus of $X^{\prime}$, and in particular they lie in $B^{\prime}$. (By (13.2.4) $X^{\prime}$ has isolated singularities outside $B^{\prime}$.) Because we are interested in the intersection of $\sum a_{i} C_{i}$ with $L^{\prime}=m\left(K_{X^{\prime}}+B^{\prime}\right)$, we only need to consider 1 -cycles on components $S$ of $B^{\prime}$ on which $\nu\left(L^{\prime}\right) \neq 0$, and focus on cycles $C_{i}$ 'horizontal' to the map $f$ defined in (14.2). They are contained in the $\Theta_{h}$ considered in (14.2) and we have a complete list of possible singularities there.

We can compute the numbers $a_{i}$ by taking a transversal slice $\Gamma_{i}$ at a general point $P_{i}$ on $C_{i}$, and reduce the computation to the surface case. Let $\mu: \tilde{\Gamma}_{i}=$ $\mu^{-1}\left(\Gamma_{i}\right) \rightarrow \Gamma_{i}$ be the resolution induced by $\mu$. Notice that the number $c_{1}^{2}+c_{2}$
does not change on blowing up a smooth point of a surface. We may assume that $\mu_{i}$ is the minimal resolution. If $P_{i}$ is an index $m_{i}$ point, then (10.8) (with $B=0$ ) tells us that
(14.3.1.2)

$$
\begin{aligned}
a_{i} & =\mu_{*}\left(K_{\tilde{\Gamma}_{i}}^{2}+c_{2}\left(\tilde{\Gamma}_{i}\right)\right)-\left(K_{\Gamma_{i}}^{2}+\hat{c}_{2}\left(\Gamma_{i}\right)\right) \\
& =\left(K_{\tilde{\Gamma}_{i}}-\mu^{*} K_{\Gamma_{i}}\right)^{2}+e_{\text {top }}\left(\mu^{-1}\left(P_{i}\right)\right)-\frac{1}{m_{i}}
\end{aligned}
$$

If the singularity is a Du Val singularity, then we can work out by explicit computation that $a_{i}$ is $\frac{3}{2}, \frac{8}{3}, \frac{15}{4}$ and $\frac{35}{6}$, when $m_{i}$ is $2,3,4$ and 6 repectively. Otherwise, $a_{i}$ is $\frac{4}{3}, \frac{3}{4}$ and $-\frac{5}{6}$, when $m_{i}$ is 3,4 and 6 respectively. Now an index 6 point is always accompanied by an index 2 point and an index 3 point, hence the sum of the corresponding $a_{i}$ is at least 2 . This completes the proof of the lemma.
14.3.2 Lemma. $L^{\prime} \cdot \hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\right) \geq L^{\prime} \cdot \hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\left(\log B^{\prime}\right)\right)-L^{\prime} \cdot\left(K_{X^{\prime}}+B^{\prime}\right) \cdot B^{\prime}$. Proof. By (10.8.8), the difference $\hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\right)-\hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\left(\log B^{\prime}\right)\right)-\left(K_{X^{\prime}}+B^{\prime}\right) \cdot B^{\prime}$ is an effective 1-cycle supported on the singular locus of $X^{\prime}$.
14.3.3 Lemma. Let $\mu: V \rightarrow X^{\prime}$ be a resolution of singularities. Then we have

$$
\mu^{*} L^{\prime} \cdot\left(K_{V}^{2}+c_{2}(V)\right) \geq 0
$$

Proof. By (14.3.1) and (14.3.2), we have
$\mu^{*} L^{\prime} \cdot\left(K_{V}^{2}+c_{2}(V)\right) \geq L^{\prime} \cdot K_{X}^{2}+L^{\prime} \cdot \hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\left(\log B^{\prime}\right)\right)-L^{\prime} \cdot\left(K_{X^{\prime}}+B^{\prime}\right) \cdot B^{\prime}$.
It follows from (10.13) that $L^{\prime} \cdot \hat{c}_{2}\left(\hat{\Omega}_{X^{\prime}}^{1}\left(\log B^{\prime}\right)\right) \geq 0 . L^{\prime}=m\left(K_{X^{\prime}}+B^{\prime}\right)$ and $\nu\left(B^{\prime},\left.L^{\prime}\right|_{B^{\prime}}\right)=1$, so that $L^{\prime} \cdot\left(K_{X^{\prime}}+B^{\prime}\right) \cdot B^{\prime}=0$. Write $K_{X^{\prime}}$ as $\sum b_{i} S_{i}$, where $b_{i} \geq 0$ and $S_{i}$ are components of $B^{\prime}$. Moreover $S_{i} \cdot L^{\prime}$ is equivalent to an effective sum of curves having zero intersection with $\left(K_{X^{\prime}}+B^{\prime}\right)$. By condition (5) of (14.2), this implies $S_{i} \cdot L^{\prime} \cdot K_{X^{\prime}} \geq 0$. Hence $L^{\prime} \cdot K_{X^{\prime}}^{2} \geq 0$. This completes the proof of the lemma.

### 14.3.4 Remarks.

(i) From the proof we see that the inequality in (14.3.3) is strict, unless the map $f_{0}$ has smooth elliptic fibres on all the components of $B$ where $\nu\left(L^{\prime}\right)=1$.
(ii) The above proof works in any dimension.
14.4 Proving that $\kappa(X)>0$. We now can prove the main theorem along the lines of the smooth case as in (14.1).
14.4.1 Theorem. [Kawamata91b] Let $X$ be a minimal 3-fold over $\mathbb{C}$. Suppose that $\nu(X)=2$. Then $\kappa(X)>0$.
Proof. Construct $X^{\prime}$ and $L^{\prime}$ as in (14.2). Let $\mu: V \rightarrow X^{\prime}$ be a desingularization of $X^{\prime}$. Since $X^{\prime}$ is $\log$ terminal, $X^{\prime}$ has only rational singularities. Therefore

$$
\begin{align*}
\chi\left(X^{\prime}, n L^{\prime}\right) & =\chi\left(V, n \mu^{*} L^{\prime}\right)  \tag{14.4.1.1}\\
& =\frac{n}{12}\left(K_{V}^{2}+c_{2}(V)\right) \cdot \mu^{*} L^{\prime}+\chi\left(\mathcal{O}_{V}\right) .
\end{align*}
$$

(14.3.3) shows that the linear term in (14.4.1.1) is nonnegative. Therefore (14.4.1.2) $\quad \chi\left(X^{\prime}, n L^{\prime}\right) \geq C \quad$ for some constant $C$.

Now look at the exact sequence:

$$
\begin{equation*}
0 \rightarrow \mathcal{O}_{X^{\prime}}\left(n L^{\prime}\left(-B^{\prime}\right)\right) \rightarrow \mathcal{O}_{X^{\prime}}\left(n L^{\prime}\right) \rightarrow \mathcal{O}_{B^{\prime}}\left(\left.n L^{\prime}\right|_{B^{\prime}}\right) \rightarrow 0 \tag{14.4.1.3}
\end{equation*}
$$

Recall that $L^{\prime}=m\left(K_{X^{\prime}}+B^{\prime}\right)$, thus $n L^{\prime}\left(-B^{\prime}\right) \equiv K_{X^{\prime}}+(n m-1) M^{\prime}$ where $M^{\prime}=K_{X^{\prime}}+B^{\prime}$. Take a general ample hyperplane section $H^{\prime}$ of $X^{\prime}$. Using the restriction exact sequence and the Kawamata-Viehweg vanishing theorem [KMM87, 1-2-5] we see that

$$
H^{i}\left(X^{\prime}, n L^{\prime}\left(-B^{\prime}\right)+l H^{\prime}\right) \simeq H^{i}\left(X^{\prime}, n L^{\prime}\left(-B^{\prime}\right)+(l+1) H^{\prime}\right)
$$

for $i \geq 2$ and $l \geq 0$. The last group vanishes when $l$ is large, thus $H^{2}\left(X^{\prime}, n L^{\prime}\left(-B^{\prime}\right)\right)=0$. Moreover, since $B^{\prime}$ is Cohen-Macaulay,

$$
h^{2}\left(B^{\prime},\left.n L^{\prime}\right|_{B^{\prime}}\right)=h^{0}\left(B^{\prime}, \omega_{B^{\prime}}\left(-\left.n L^{\prime}\right|_{B^{\prime}}\right)\right)=0
$$

for $n$ large. Therefore we have $H^{2}\left(X^{\prime}, n L^{\prime}\right)=0$ for large $n$. Combined with (14.4.1.2), this shows that

$$
h^{0}\left(X^{\prime}, n L^{\prime}\right) \geq h^{1}\left(X^{\prime}, n L^{\prime}\right)+C .
$$

Thus it is sufficient to prove that $h^{1}\left(X^{\prime}, n L^{\prime}\right)$ grows linearly with $n$. Note that $\chi\left(X^{\prime}, K_{X^{\prime}}+(n-1) L^{\prime}\right)=-\chi\left(X^{\prime},(1-n) L^{\prime}\right)$ has the same linear term as in (14.4.1.1). Hence it follows from (14.4.1.3) that $\chi\left(B^{\prime},\left.n L^{\prime}\right|_{B^{\prime}}\right)$ is actually a constant. Then (12.1.1) together with the vanishing of $H^{2}\left(B^{\prime},\left.n L^{\prime}\right|_{B^{\prime}}\right)$ implies that both $h^{0}\left(B^{\prime},\left.n L^{\prime}\right|_{B^{\prime}}\right)$ and $h^{1}\left(B^{\prime},\left.n L^{\prime}\right|_{B^{\prime}}\right)$ grow with $n$. We have

$$
H^{1}\left(X^{\prime}, n L^{\prime}\right) \rightarrow H^{1}\left(B^{\prime},\left.n L^{\prime}\right|_{B^{\prime}}\right) \rightarrow H^{2}\left(X^{\prime}, n L^{\prime}\left(-B^{\prime}\right)\right)=0 .
$$

This shows that $h^{1}\left(X, n L^{\prime}\right)$ grows with $n$ and completes the proof of the theorem.

## 15. LOG ELLIPTIC FIBER SPACES

JÁnos Kollár

The aim of this chapter is to complete the proof of abundance for threefolds. Instead of the cohomological approach of [Kawamata85] we present a rather geometric one. Many of the arguments work for an arbitrary nef divisor $B$ such that $\nu(B)=2$ and $\kappa(B) \geq 1$. The underlying variety can have arbitrary dimension or even positive characteristic. We however formulate everything for a klt divisor $K_{X}+\Delta_{X}$ in characteristic zero, where the necessary flips are known to exist.
15.1 Definition. (15.1.1) A $\log$ elliptic fiber space is a proper morphism $g$ : $\left(V, \Delta_{V}\right) \rightarrow W$ such that $g_{*} \mathcal{O}_{V}=\mathcal{O}_{W}$, the generic fiber $E_{g}$ is an irreducible curve and $\left(K_{V}+\Delta_{V}\right) \cdot E_{g}=0$.
(15.1.2) Let $\left(X, \Delta_{X}\right)$ be a log variety. A log elliptic structure on $X$ is a diagram

where $h$ is a birational morphism, $g:\left(V, \Delta_{V}\right) \rightarrow W$ is a log elliptic fiber space and $K_{V}+\Delta_{V}=h^{*}\left(K_{X}+\Delta_{X}\right)+F$, where $F$ is effective and $\operatorname{Supp} F$ contains every $h$-exceptional divisor.
15.1.3 Comments. The second definition is motivated by two examples. First, assume that $\left(V, \Delta_{V}\right)$ is a log elliptic fiber space and assume that $\left(X, \Delta_{X}\right)$ is obtained from $\left(V, \Delta_{V}\right)$ by $\left(K_{V}+\Delta_{V}\right)$-extremal contractions and flips. Then $\left(X, \Delta_{X}\right)$ has a log elliptic structure (we may have to blow up $V$ a little).

Second, if $X$ has terminal singularities, $\Delta_{X}=0$ and $X$ is birational to an elliptic fiber space $(V, 0)$ then $X$ has an elliptic structure.
15.2 Proposition. Let $\left(X, \Delta_{X}\right)$ be a proper klt variety. Assume that $K_{X}+$ $\Delta_{X}$ is nef and that $X$ has a log elliptic structure. Then there is an open set $U \subset X$ and a proper morphism $f_{U}: U \rightarrow Z$ which is a log elliptic fiber space.

Proof. Let $E_{g} \subset V$ be the generic fiber of $g$. Then

$$
0=E_{g} \cdot\left(K_{V}+\Delta_{V}\right)=E_{g} \cdot h^{*}\left(K_{X}+\Delta_{X}\right)+E_{g} \cdot F \geq E_{g} \cdot F
$$

Thus $F$ is disjoint from $E_{g}$ and $h$ is an isomorphism in a neighborhood of $E_{g}$.

For higher dimensional fibers the situation is more complicated. The following result (which is not used in the sequel) generalizes [Grassi91, 1.8].
15.3 Theorem. Let $X$ be a proper variety with $\mathbb{Q}$-factorial terminal singularities. Assume that $m K_{X}=0$ for some $m>0$ and $\rho(X)=1$. Let $p: X \rightarrow Z$ be a dominant rational map with connected fibers. Then $p^{-1}(z)$ is of general type for every general $z \in Z$.

Proof. Let $g: Y \rightarrow X$ be a proper birational morphism such that $f=p \circ g$ : $Y \rightarrow Z$ is a morphism. Let $E \subset Y$ be the exceptional divisor of $g$. We may assume that $Y$ is smooth. Let $H \subset Z$ be a divisor. Then $g\left(f^{*}(H)\right)$ is an effective divisor on $X$, hence ample.

$$
g^{*}\left(g\left(f^{*}(H)\right)\right)=f^{*}(H)+F_{1} \quad \text { where Supp } F_{1} \subset E
$$

Let $z \in Z-H$ be a point such that $f^{-1}(z)$ is smooth and $g \mid f^{-1}(z)$ is birational. Then

$$
g^{*}\left(g\left(f^{*}(H)\right)\right)\left|f^{-1}(z)=F_{1}\right| f^{-1}(z)
$$

is the pull back of an ample divisor by the birational morphism $g \mid f^{-1}(z)$. In particular it is big. On the other hand, $K_{Y}=g^{*} K_{X}+F_{2}$ where $\operatorname{Supp} F_{2}=E$. Thus

$$
m K_{f^{-1}(z)}=m K_{Y}\left|f^{-1}(z)=m F_{2}\right| f^{-1}(z)
$$

Since $\operatorname{Supp} F_{1} \subset \operatorname{Supp} F_{2}$ this implies that $K_{f^{-1}(z)}$ is big.
15.4 Theorem. Let $\left(X, \Delta_{X}\right)$ be a projective $\mathbb{Q}$-factorial threefold such that $K_{X}+\Delta_{X}$ is klt. Assume that
(15.4.1) $K_{X}+\Delta_{X}$ is nef;
(15.4.2) $\operatorname{dim}\left|m\left(K_{X}+\Delta_{X}\right)\right| \geq 1$ for some $m>0$;
(15.4.3) there is an open set $U \subset X$ and a proper morphism $f_{U}: U \rightarrow Z$ which is a log elliptic fiber space.

Then $K_{X}+\Delta_{X}$ is eventually free.
15.4.4 Remark. If $p: X \rightarrow Y$ is a morphism such that $K_{X}+\Delta_{X}=p^{*}\left(K_{Y}+\right.$ $\Delta_{Y}$ ) then $K_{X}+\Delta_{X}$ is eventually free iff $K_{Y}+\Delta_{Y}$ is. Similarly, if $p: X \rightarrow Y$
is a ( $K_{X}+\Delta$ )-flop then $K_{X}+\Delta_{X}$ is eventually free iff $K_{Y}+p_{*}\left(\Delta_{X}\right)$ is. We use these observations to change $X$.
15.5 End of the proof of (11.1.1). Let $X$ be a minimal threefold. The only case still open is when $\nu(X)=2$. We woud like to check the conditions of (15.4) in case $\Delta_{X}=0$. (15.4.1) is assumed and (14.4.1) shows (15.4.2). (15.4.3) requires a little work.

Lt ( $X^{\prime}, B^{\prime}$ ) be as in (14.2). $B^{\prime}$ is a semi log canonical surface with $\nu\left(B^{\prime}\right)=$ 1. Thus by (11.3.1) it has an irreducible component which is birational to either a ruled or to an elliptic surface. We already know that $\operatorname{dim} \mid m\left(K_{X}+\right.$ $\left.\Delta_{X}\right) \mid \geq 1$. Assume that we can construct ( $X^{\prime}, B^{\prime}$ ) such that $B^{\prime}$ moves in a pencil. We obtain that $X^{\prime}$ contains a pencil of ruled or elliptic surfaces. $X^{\prime}$ is not uniruled, thus it has a pencil of elliptic surfaces. Therefore $X$ is birational to an elliptic threefold, hence (15.2) implies (15.4.3).

Let us go back to the construction in (14.2) which was started in (13.2). (We use the notation employed there.) If $D \in\left|m\left(K_{X}+\Delta_{X}\right)\right|$ moves in a pencil then we can choose $\mu: X_{0} \rightarrow X$ such that $\tilde{D}$ still moves in a pencil. This pencil survives in all the contractions and flips. At the end we obtain $\left(X^{\prime}, B^{\prime}\right)$ as in (14.2) such that $B^{\prime}$ moves in a pencil $\left\{B_{t}^{\prime}\right\}$ and $\left(X^{\prime}, B_{t}^{\prime}\right)$ is $\log$ canonical for general $t$. At least one of the moving components of $B_{t}^{\prime}$ has $\nu\left(B_{t}^{\prime}\right)=1$. Thus the above argument applies and (15.4) completes the proof of the abundance theorem for threefolds.
15.6 Definition. We say that an effective divisor $D \subset X$ is $\left(K_{X}+\Delta_{X}\right)$ trivially connected if for any two points $x_{1}, x_{2} \in D$ there is a connected curve $x_{1}, x_{2} \in C \subset D$ such that $K_{X}+\Delta_{X}$ is numerically trivial on every irreducible component of $C$.
15.7 Lemma. Assume (15.4.1 and 2). Let $D \subset X$ be $\left(K_{X}+\Delta_{X}\right)$-trivially connected. Then one of the following holds:
(15.7.1) $K_{X}+\Delta_{X}$ is eventually free and is composed of a pencil,
(15.7.2) there is an effective divisor $D^{\prime}$ and natural numbers $d$, $m$ such that $d D+D^{\prime} \in\left|m\left(K_{X}+\Delta_{X}\right)\right|, \operatorname{Supp} D \not \subset \operatorname{Supp} D^{\prime}$ and $D \cap D^{\prime} \neq \emptyset$.

Proof. Let $\left|m\left(K_{X}+\Delta_{X}\right)\right|=F+|M|$ where $F$ is the fixed part. Assume first that $|M|$ is composed of a free pencil. Let $p: X \rightarrow C$ be the corresponding morphism with connected fibers. Assume that we can not find $d D+D^{\prime}$ as required. Then $\operatorname{Supp} D$ is a fiber of $p$, hence $F$ is contained in a union of fibers. Since $F$ is nef, $F$ is the sum of rational multiples of fibers, hence some multiple of $K_{X}+\Delta_{X}$ is the pull-back of an ample divisor from $C$.

Otherwise there is a pencil $F^{\prime}+\left|N_{t}\right| \subset\left|m\left(K_{X}+\Delta_{X}\right)\right|$ such that every $N_{t}$ is connected and $\left|N_{t}\right|$ has a base point $b \in X . D \subset X$ is $\left(K_{X}+\Delta_{X}\right)$-trivially connected, thus if $B \in\left|m\left(K_{X}+\Delta_{X}\right)\right|$ intersects $D$ then $D$ is an irreducible
component of $B$. If $b \in D$ then $D \subset F$ and any general $N_{t}$ intersects $D$ but is different from it. If $b \notin D$ then there is a $t_{0}$ such that $N_{t_{0}}$ intersects $D . N_{t_{0}}$ is connected and also contains $b$, thus we are again done.
15.8 Lemma. Assumptions as in (15.7) and assume that (15.7.2) holds. Then $K_{X}+\Delta_{X}+\epsilon D$ is not nef for $\epsilon>0$.
Proof. By assumption there is an irreducible curve $C \subset D$ such that $C \cdot\left(K_{X}+\right.$ $\left.\Delta_{X}\right)=0$ satisfying $C \cap D^{\prime} \neq \emptyset$ and $C \not \subset D^{\prime}$. Thus

$$
0=C \cdot\left(d D+D^{\prime}\right)=d C \cdot D+C \cdot D^{\prime}, \quad \text { hence } \quad C \cdot D<0
$$

Therefore $C \cdot\left(\left(K_{X}+\Delta_{X}\right)+\epsilon D\right)=\epsilon C \cdot D<0$.
15.9 Corollary. Assumptions as in (15.4). Then one of the following holds:
(15.9.1) $\left|n\left(K_{X}+\Delta_{X}\right)\right|$ is composed of a free pencil for some $n>0$; or
(15.9.2) there is a $\log$ variety $\left(X^{\prime}, \Delta_{X^{\prime}}\right)$ which is $\log$ birational to $\left(X, \Delta_{X}\right)$ and satisfies all the assumptions of (15.4) and such that $X^{\prime}$ does not contain any $\left(K_{X^{\prime}}+\Delta_{X^{\prime}}\right)$-trivially connected divisors.

Proof. Assume that $X$ contains a $\left(K_{X}+\Delta_{X}\right)$-trivially connected divisor $D$. Then either (15.7.1) holds or $K_{X}+\Delta_{X}+\epsilon D$ is not nef. After a sequence of $D$-flops (with respect to $K_{X}+\Delta_{X}$ ) the birational transform of $D$ becomes contractible. For this it is sufficient to observe that the birational transform of $D$ under a sequence of flops stays $(K+\Delta)$-trivially connected. The general fiber of the elliptic fibration is disjoint from $D$, thus (15.4.3) is preserved under flops and $(K+\Delta)$-trivial contractions. Repeating this procedure, we eventually stop at $X^{\prime}$.
15.10 Theorem. Assumptions as in (15.4). Assume furthermore that $X$ does not contain any $\left(K_{X}+\Delta_{X}\right)$-trivially connected divisors. Then $f_{U}$ extends to a morphism $f: X \rightarrow \bar{Z}$ with 1-dimensional fibers.
Proof. By shrinking $Z$ we may assume that $f_{U}$ is flat. Thus we get a morphism $Z \rightarrow \operatorname{Chow}(X)$. (See [Hodge-Pedoe52, X.6-8] for basic results about Chow varieties.) Let $\bar{Z}$ be the normalization of the closure of the image and let $g: \bar{U} \rightarrow \bar{Z}$ be the universal family. Let $u: \bar{U} \rightarrow X$ be the natural morphism. We prove that $u$ is an isomorphism.
$u$ is an isomorphism over $g^{-1}(Z)$. Assume that $F \subset \bar{U}$ is a divisor contracted by $u$. Then $g(F)$ is at most one dimensional. Since $g$ has one dimensional fibers, $g(F)$ is one dimensional. Let $E=g^{-1}(g(F)) . \operatorname{dim} u(E)=2$ since a 1-dimensional subvariety of $X$ supports only countably many different cycles in Chow $(X)$. (This is the point where we need Chow instead of Hilb.) Thus there are divisors $E_{1}, E_{2} \subset E$ such that

$$
\operatorname{dim} u\left(E_{1}\right)=2 ; \quad \operatorname{dim} u\left(E_{2}\right) \leq 1 \quad \text { and } \quad E_{1} \cap E_{2} \text { dominates } g(F)
$$

We claim that $u\left(E_{1}\right)$ is $\left(K_{X}+\Delta_{X}\right)$-trivially connected. Indeed, $u\left(E_{1} \cap E_{2}\right) \subset$ $u\left(E_{2}\right)$ and every curve in $u\left(E_{2}\right)$ has zero intersection with $K_{X}+\Delta_{X}$. Any two points of $u\left(E_{1}\right)$ can be connected by images of fibers of $E_{1} \rightarrow g(F)$ and by $u\left(E_{1} \cap E_{2}\right)$.

This contradiction shows that $u$ does not contract any divisors. Since $X$ is $\mathbb{Q}$-factorial, $u$ can not contract curves, and thus $u$ is an isomorphism.
15.11 Lemma. Let $X$ be a variety with $\log$ terminal singularities. Let $f$ : $X \rightarrow Z$ be a proper morphism onto a normal variety $Z$ such that every fiber has dimension $k$ for some fixed $k$. If $\operatorname{dim} Z>2$ then assume that $K_{Z}$ is $\mathbb{Q}$-Cartier. Then $Z$ has only log terminal singularities.

Proof. Choose a projective embedding of $X$. Fix $z \in Z$. Let $H \subset X$ be a complete intersection of $k$ general hyperplanes. $H \rightarrow Z$ is dominant and we may assume that $H \rightarrow Z$ is finite over $z . H$ has a log terminal singularities (cf. [Reid80, 1.13]) thus by (20.3.1) $Z$ has a $\log$ terminal singularity at $z$.
15.11.1 Remark. Shokurov pointed out that under the assumptions of (15.11) if $X$ is $\mathbb{Q}$-factorial then so is $Z$.
15.12 Proposition. Let $f:\left(X, \Delta_{X}\right) \rightarrow Z$ be a log elliptic fiber space with 1-dimensional fibers. Assume that $\left(X, \Delta_{X}\right)$ is lc and nef. Then there is a line bundle $L$ on $Z$ such that

$$
n\left(K_{X}+\Delta_{X}\right) \sim f^{*} L \quad \text { for some } n>0
$$

Proof. A general fiber $E_{g}$ of $f$ is either an elliptic curve (which is disjoint from $\Delta_{X}$ ) or is a rational curve. In either case a multiple of $K_{X}+\Delta_{X}$ is linearly equivalent to zero on the generic fiber. Thus there is a (not necessarily effective) divisor $D$ which is disjoint from $E_{g}$ and is linearly equivalent to $n_{0}\left(K_{X}+\Delta_{X}\right)$ for some $n_{0}>0$. Let $C_{i} \subset Z$ be the irreducible components of $f(\operatorname{Supp} D)$. We can write $D=\sum D_{i}$ where the $D_{i}$ are those components that map onto $C_{i}$. Let $z_{i}$ be a general point of $C_{i}$. Then $D_{i}$ is nef on $f^{-1}\left(z_{i}\right)$, thus $D_{i}$ is a rational multiple of $f^{*}\left(C_{i}\right)$. Hence $n_{i} D_{i}=f^{*}\left(m_{i} C_{i}\right)$ for some $n_{i}>0$ (possibly $m_{i}<0$ ). Choose $M$ such that

$$
M \sum \frac{m_{i}}{n_{i}} C_{i}
$$

is Cartier. Then

$$
M n_{0}\left(K_{X}+\Delta_{X}\right) \sim f^{*} \mathcal{O}_{Z}\left(M \sum \frac{m_{i}}{n_{i}} C_{i}\right)
$$

(15.13) Proof of (15.4). If $\left|n\left(K_{X}+\Delta_{X}\right)\right|$ is composed of a base point free pencil then we are done. Otherwise $\nu\left(K_{X}+\Delta_{X}\right) \geq 2$.

By (15.9) there is a series of flops and $(K+\Delta)$-trivial contractions $X \rightarrow$ $X^{\prime}$ such that $X^{\prime}$ does not contain $(K+\Delta)$-trivially connected surfaces. By (15.4.4) it is sufficient to show that $K_{X^{\prime}}+\Delta_{X^{\prime}}$ is eventually free. (15.10) gives a proper morphism $f: X^{\prime} \rightarrow \bar{Z}$ and by (15.12) there is a line bundle $L$ on $\bar{Z}$ such that $n\left(K_{X^{\prime}}+\Delta_{X^{\prime}}\right) \sim f^{*} L$.

I claim that $L$ is ample. This is proved using the Nakai-Moishezon criterion. Let $H$ be ample on $X$ and let $E_{g}$ be a general fiber of $f$. Then

$$
\left(E_{g} \cdot H\right)(L \cdot L)=H \cdot f^{*} L \cdot f^{*} L=n^{2} H \cdot\left(K_{X^{\prime}}+\Delta_{X^{\prime}}\right) \cdot\left(K_{X^{\prime}}+\Delta_{X^{\prime}}\right)>0 .
$$

If $C \subset Z$ is an irreducible curve such that $C \cdot L=0$ then $K_{X^{\prime}}+\Delta_{X^{\prime}}$ is numerically trivial on $f^{-1}(C)$, a contradiction. Thus $L$ is ample, and hence a suitable multiple of $L$ is generated by global sections.

## 16. ADJUNCTION OF LOG DIVISORS

Alessio Corti

In this chapter we discuss several matters connected with the adjunction formula for a Weil divisor $S \subset X$ inside a normal space $X$. The first goal is to define a different Diff which is a $\mathbb{Q}$-divisor on $S$ so that the following adjunction formula holds:

$$
K_{S}+\mathrm{Diff}=K_{X}+\left.S\right|_{S}
$$

[Shokurov91,Ch.3] defines the different as a divisor on the normalization $S^{\nu}$ of $S$, and uses the notion to establish some elementary properties of log terminal singularities. However, it is desirable to deal with the reduced part of the boundary of a log divisor without normalizing it. For this reason we define the different directly on $S$.

Once the different is defined, we use it to relate properties of $(X, S)$ to ( $S$, Diff).

We begin with some preliminaries on Weil divisors on nonnormal varieties. In the following, $X$ is a pure dimensional reduced scheme. After (16.7) we always assume that $X$ is defined over an algebraically closed field of characteristic zero. $X$ may be reducible and not necessarily $S_{2} . K(X)$ denotes the sheaf of total quotient rings (see e.g. [Hartshorne77, II.6]).

### 16.1 Definition.

(16.1.1) A Weil divisorial subsheaf is a coherent $\mathcal{O}_{X}$-module $\mathcal{L}$, which is principal in codimension one and saturated, together with the choice of an embedding $\mathcal{L} \subset K(X)$. The condition that $\mathcal{L}$ is free in codimension one implies $\mathcal{L} \cong \mathcal{L}^{* *}$, provided $X$ is $S_{2}$. The embedding $\mathcal{L} \subset K(X)$ is very important, although, following common useage in the literature, I will occasionally be sloppy about it (see 16.3.3).
(16.1.2) Define the product $\mathcal{L} \cdot \mathcal{L}^{\prime} \subset K(X)$ in the natural way (i.e. $\mathcal{L} \cdot \mathcal{L}^{\prime}$ is the saturation of the product of sheaves $\left.\mathcal{L} \mathcal{L}^{\prime} \subset K(X)\right)$. Note that in general the natural homomorphism $\mathcal{L} \otimes \mathcal{L}^{\prime} \rightarrow \mathcal{L} \cdot \mathcal{L}^{\prime}$ is neither injective nor surjective (it is, however, an isomorphism, whenever $\mathcal{L}$ or $\mathcal{L}^{\prime}$ is locally $\mathcal{O}_{X}$-free). We
also write $\mathcal{L}^{[n]}$ for the product of $\mathcal{L}$ with itself $n$-times. With these laws, the set of Weil divisorial subsheaves is a group which we denote by $\mathrm{WSh}(X)$. In a natural way $\mathcal{L}^{*}=\operatorname{Hom}\left(\mathcal{L}, \mathcal{O}_{X}\right)=\mathcal{L}^{-1}=\left\{x \in K(X) \mid x \cdot \mathcal{L} \subset \mathcal{O}_{X}\right\} \subset K(X)$.

Equivalently, let $\operatorname{CDiv}(U)$ be the group of Cartier divisors on a scheme $U$. Then

$$
\mathrm{WSh}(X)=\operatorname{proj} \lim \mathrm{CDiv}(X \backslash S)
$$

where the limit is over all closed subschemes $S \subset X$ such that $\operatorname{codim}_{X} S \geq 2$.
If $X$ is normal then this is the usual definition. However for nonnormal schemes unexpected things can happen. Let for instance

$$
X=\operatorname{Spec} \mathbb{C}\left[x, y, z, z^{-1}\right] /\left(x^{2}-z y^{2}\right)
$$

The ideals $(x)$ and ( $y$ ) define different Weil divisorial subsheaves such that $(x)^{[2]}=(y)^{[2]}$.
(16.1.3) The group of $\mathbb{Q}$-Weil divisorial sheaves is defined as $\operatorname{WSh}(X)_{\mathbb{Q}}=$ $\mathrm{W} \operatorname{Sh}(X) \otimes \mathbb{Q}$.
(16.1.4) To each unit $x \in K(X)^{*}$ there is a naturally associated Weil divisorial subsheaf $(x)=x \cdot \mathcal{O}_{X} \subset K(X)$. We say that two Weil divisorial subsheaves $\mathcal{L}$ and $\mathcal{L}^{\prime}$ are linearly equivalent and write $\mathcal{L} \sim \mathcal{L}^{\prime}$ if $\mathcal{L}^{-1} \cdot \mathcal{L}^{\prime}=(x)$ for some $x \in K(X)^{*}$.
(16.1.5) If $\mathcal{L}$ is a Weil divisorial subsheaf, we define the support of $\mathcal{L}$ to be the Zariski closed subset $\operatorname{Supp}(\mathcal{L}) \subset X$ of points where $\mathcal{L} \neq \mathcal{O}_{X}$.
(16.1.6) $\mathcal{L} \subset K(X)$ is effective if $\mathcal{O}_{X} \subset \mathcal{L} \subset K(X)$.

### 16.2 Definition.

(16.2.1) A Weil divisor on $X$ is a formal linear combination:

$$
D=\sum n_{\Gamma} \Gamma
$$

where the sum extends over all points of codimension one $\Gamma \subset X$ such that $\mathcal{O}_{X, \Gamma}$ is a DVR, and $n_{\Gamma}$ are integers, only finitely many of which are nonzero. The group of all Weil divisors is denoted by $\operatorname{WDiv}(X)$. As in (16.1.3), $\operatorname{WDiv}(X)_{\mathbb{Q}}=\operatorname{WDiv}(X) \otimes \mathbb{Q}$
(16.2.2) There is a natural injective group homomorphism $\operatorname{WDiv}(X) \ni$ $D \mapsto \mathcal{O}(D) \in \mathrm{WSh}(X)$. Let $\Gamma \subset X$ be a codimension one prime of $X$, then $\mathcal{O}(D)$ is uniquely determined by $\mathcal{O}(D)_{\Gamma}=\mathcal{O}_{X, \Gamma}$ if $X$ is not regular at $\Gamma$, and $\mathcal{O}(D)_{\Gamma}=t^{n_{\Gamma}} \cdot \mathcal{O}_{X, \Gamma}$ if $\mathcal{O}_{X, \Gamma}$ is a DVR.

If $\mathcal{L}$ is a Weil divisorial subsheaf, $\mathcal{L}(D)$ as usual denotes $\mathcal{L} \cdot \mathcal{O}(D)$.
We say that $D$ and $D^{\prime}$ are linearly equivalent if the corresponding sheaves are.

Also, perhaps inappropriately, we say that a Weil divisorial subsheaf $\mathcal{L} \subset$ $K(X)$ is a Weil divisor if $\mathcal{L}=\mathcal{O}(D)$ for some Weil divisor $D$. Of course, this
is equivalent to saying that no codimension one component of the support of $\mathcal{L}$ is contained in the singular locus of $X$.

### 16.3 Remarks and more definitions.

(16.3.1) The inclusion $\operatorname{WDiv}(X) \subset \mathrm{WSh}(X)$ induces an isomorphism

$$
\operatorname{WDiv}(X) / \sim \cong \operatorname{WSh}(X) / \sim,
$$

and we denote any of these two groups by Weil $(X)$.
(16.3.2) $\mathcal{O}_{X} \subset K(X)$ is a Weil divisorial subsheaf precisely when $X$ is $S_{2}$.
(16.3.3) The dualizing sheaf $\omega_{X}$ (as in [Hartshorne77, III.7], that is, $\omega_{X}=$ $H^{-d}\left(\omega_{X}\right)$ if $\omega_{X}$ is the normalized dualizing complex) is torsion free of rank one, and admits therefore an embedding $\omega_{X} \subset K(X)$. Since we also know that $\omega_{X}$ is saturated (see e.g. [Reid80, App. to $\left.\S 1\right]$ ), $\omega_{X}$ is a Weil divisorial subsheaf precisely when $X$ is Gorenstein in codimension one. This is why later (16.5) we shall assume this condition (which is satisfied for example if $X$ has normal crossings in codimension one). If this is the case then with an appropriate choice of embedding $\omega_{X} \subset K(X), \omega_{X}$ is actually a Weil divisor, whose linear equivalence class is denoted by $K_{X}$.
(16.3.4) Weil divisors and sheaves are codimension one constructions. This means that $X$ may always be replaced with any open subset $U \subset X$ such that $\operatorname{codim}_{X}(X \backslash U) \geq 2$. This principle is used in many natural constructions like pullbacks and restrictions, as well as in many proofs (sometimes without explicit mention).
(16.3.5) Let $p: X^{\prime} \rightarrow X$ be a finite dominant morphism. There is a natural pullback

$$
p^{w}: \mathrm{WSh}(X) \rightarrow \mathrm{WSh}\left(X^{\prime}\right)
$$

This is defined on $\mathcal{L}$ by taking $U \subset X$ open with $\operatorname{codim}_{X}(X \backslash U) \geq 2$, and such that $\mathcal{L}$ is locally free on $U$. Then on $V=p^{-1}(U), p^{w}(\mathcal{L})=p^{*}(\mathcal{L})$ is a locally free subsheaf of $K(V)$, and defines a Weil divisorial subsheaf on $X^{\prime}$ (16.3.4).
(16.3.6) Similarly, let $i: S \hookrightarrow X$ be a subscheme of pure codimension one. Denote by $\mathrm{WSh}_{S}(X)$ the subgroup of sheaves $\mathcal{L}$ which are $\mathbb{Q}$-Cartier at all points $P \subset S$ of codimension one, and such that $S$ and $\operatorname{Supp}(\mathcal{L})$ have no common irreducible components (if these conditions are satisfied we say that $\mathcal{L}$ has good support on $S$ ). Then we have a natural restriction homomorphism:

$$
i^{w}: \mathrm{WSh}_{S}(X) \rightarrow \mathrm{WSh}(S)_{\mathbb{Q}} .
$$

This is defined as follows. If $\mathcal{L}$ is Cartier at points $P \subset S$ of codimension one, let $U \subset X$ be an open subset such that $\operatorname{codim}_{X}(X \backslash U) \geq 2, \operatorname{codim}_{S}(S \backslash U) \geq 2$ and $\mathcal{L}$ is Cartier on $U$. Then on $V=S \cap U, i^{w} \mathcal{L}$ is the usual restriction of
a Cartier divisor (and, because $\mathcal{L}$ has good support on $S, \mathcal{L} \subset K(X)$ induces $\left.i^{w} \mathcal{L} \subset K(S)\right)$. This determines $i^{w} \mathcal{L}$ on $S$. If $\mathcal{L} \in \mathrm{WSh}_{S}(X)$, then $\mathcal{L}^{[n]}$ is Cartier at points $P \subset S$ of codimension one for some $n>0 . i^{w} \mathcal{L}$ is defined to be $\frac{1}{n} i^{w} \mathcal{L}^{[n]}$. This is independent of the choice of $n$. We also write $\mathcal{L} \mid S$ instead of $i^{w}(\mathcal{L})$. The whole point of this construction is of course that we want to define $i^{w}$ in such a way that it is functorial and a group homomorphism.

Next we state the adjunction formula for a divisor $i: S \hookrightarrow X$. If $\mathcal{F}$ is a sheaf on $X$, we write $i^{*} \mathcal{F}=\mathcal{F} \otimes \mathcal{O}_{S}$ and

$$
i^{[*]} \mathcal{F} \xlongequal{\text { def }} \text { saturation of }\left(i^{*} \mathcal{F} / \operatorname{Torsion}_{\mathcal{O}_{S}}\left(i^{*} \mathcal{F}\right)\right)
$$

16.4 Proposition. Let $X$ be a normal scheme (actually it is enough that $X$ is $S_{2}$ ), and $i: S \hookrightarrow X$ a reduced subscheme of pure codimension one. Then there is a canonical isomorphism:

$$
\omega_{S}=i^{[*]} \omega_{X}(S)
$$

In particular:
(16.4.1) If $X$ is $S_{3}$ and $S$ is a Cartier divisor, then $\omega_{S}=\omega_{X} \otimes \mathcal{O}_{X}(S) \otimes \mathcal{O}_{S}$.
(16.4.2) If $\omega_{X}(S)$ is locally free and $S$ is $S_{2}$, then $\omega_{S}=\omega_{X}(S) \otimes \mathcal{O}_{S}$. In particular $\omega_{S}$ is locally free and $S$ is Gorenstein if it is CM (=CohenMacaulay).
(16.4.3) If $\omega_{X}(S)$ is Cartier at every codimension one point $P \in S$, then $\omega_{S}=i^{w} \omega_{X}(S)$. In particular then $S$ is Gorenstein in codimension one, and choosing suitable embeddings we may write the above isomorphism in the form $K_{S}=K_{X}+S \mid S$.
Proof. By assumption $X$ is CM outside a set $Z$ of codimension three; by considering $X \backslash Z$ we may assume that $X$ is CM.

Along the lines of [Hartshorne77, III.7] it is easy to check that $\omega_{S}=$ $\operatorname{Ext}^{1}\left(\mathcal{O}_{S}, \dot{\omega}_{X}\right)$ is a dualizing sheaf for $S$. Applying $\operatorname{Hom}_{\mathcal{O}_{X}}\left(\cdot, \omega_{X}\right)$ to the exact sequence:

$$
0 \rightarrow \mathcal{O}_{X}(-S) \rightarrow \mathcal{O}_{X} \rightarrow \mathcal{O}_{S} \rightarrow 0
$$

(since $S$ is a Weil divisor, $\mathcal{I}_{S}=\mathcal{O}_{X}(-S) \subset \mathcal{O}_{X}$, with the notation of (16.2.2)), we obtain an exact sequence:

$$
0 \rightarrow \omega_{X} \rightarrow \omega_{X}(S) \rightarrow \omega_{S} \rightarrow 0
$$

which fits into a commutative diagram (with exact rows):

This shows that $\alpha: \omega_{X}(S) \otimes \mathcal{O}_{S} \rightarrow \omega_{S}$ is surjective. $S$ is a Weil divisor, and hence $X$ is smooth at every generic point of $S$. Therefore $\alpha$ is an isomorphism at generic points of $S$, so $\omega_{X}(S) \otimes \mathcal{O}_{S} / \operatorname{Torsion}_{\mathcal{O}_{S}}\left(\omega_{X}(S) \otimes \mathcal{O}_{S}\right) \cong \omega_{S}$, which is what we want.
16.4.4 Example. Let $A \subset \mathbb{P}^{n-1}$ be a smooth, projectively normal, Abelian surface and let $X \subset \mathbb{P}^{n}$ be the cone over $A$ with vertex $x \in X$. Then $X$ is normal, lc and $\omega_{X} \cong \mathcal{O}_{X}(-1)$. However $X$ is not $S_{3}$. Let $x \in H \subset X$ be a hyperplane section, smooth outside $x . H$ is not normal; let $p: \bar{H} \rightarrow H$ be the normalisation. Then

$$
\omega_{H}=p_{*}\left(\mathcal{O}_{\bar{H}}\right) \neq \mathcal{O}_{H}=\operatorname{Ext}^{1}\left(\mathcal{O}_{H}, \omega_{X}\right)
$$

The aim is to generalize the adjunction formula (16.4.3) to the case where $\omega_{X}(S)$ is only $\mathbb{Q}$-Cartier at codimension one points $P \subset S$. This is accomplished in the following:
16.5 Proposition - Definition. Let $X$ be a normal scheme, $i: S \hookrightarrow X$ a reduced subscheme of pure codimension one. Assume that $S$ is Gorenstein in codimension one and that $\omega_{X}(S) \in \mathrm{WSh}_{S}(X)$. Then there is a naturally defined effective different $\mathcal{D}$ iff $(0) \in \mathrm{WSh}(S)_{\mathbb{Q}}$ so that:

$$
\omega_{S} \cdot \mathcal{D} i f f(0)=i^{w} \omega_{X}(S)
$$

If $B \in \mathrm{WSh}_{S}(X)_{\mathbb{Q}}$, we also define the different of $B$ by $\operatorname{Diff}(B)=\mathcal{D}$ iff(0). $i^{w} B$.

Proof. We systematically remove codimension 2 subsets $Z \subset S$, whenever needed, without warning.

From the adjunction formula (16.4) we know that $\omega_{S}=\omega_{X}(S)_{S}$. Suppose that $\omega_{X}(S)^{[n]}$ is Cartier at every codimension one point $P \in S$. Consider the sequence of maps

$$
\left(\omega_{X}(S) \otimes \mathcal{O}_{S}\right)^{\otimes n} \cong \omega_{X}(S)^{\otimes n} \otimes \mathcal{O}_{S}^{\otimes n} \rightarrow \omega_{X}(S)^{\otimes n} \otimes \mathcal{O}_{S} \rightarrow \omega_{X}(S)^{[n]} \otimes \mathcal{O}_{S}
$$

Taking the quotient by the torsion submodules we obtain

$$
\omega_{S}^{[n]} \xrightarrow{\delta} \omega_{X}(S)^{[n]} \otimes \mathcal{O}_{S}
$$

which is an isomorphism at the generic points of $S$ because $X$ is normal. $\delta$ defines a Weil divisorial subsheaf $\mathcal{D}$ on $S$ so that $\omega_{S}^{[n]} \cdot \mathcal{D}=i^{w} \omega_{X}(S)^{[n]}$. Since the isomorphism of the adjunction formula is natural, $\mathcal{D}$ is well defined (i.e., it does not depend on the embedding $\left.\omega_{X}(S) \subset K(X)\right)$. Set $\operatorname{Diff}(0)=\frac{1}{n} \mathcal{D}$.

We now apply the different to study $\log$ canonical and log terminal singularities. The nice fact is that if $K_{X}+S$ is $\log$ canonical in codimension two, the different is actually a Weil divisor (i.e., no codimension one component of the support of $\mathcal{D}$ iff is contained in the singular locus of $S$ ). Also, under the same assumptions, we compute the different.
16.6 Proposition. Let $X$ be a normal space, $S \subset X$ a reduced subscheme of pure codimension one and $B$ a $\mathbb{Q}$-Weil divisor. Assume that $K_{X}+S+B$ is log canonical in codimension two. Then $S$ has normal crossings in codimension one, so the assumptions of (16.5) are satisfied. Moreover the different $\mathcal{D}$ if $f(B)$ is a $\mathbb{Q}$-Weil divisor (that is, no codimension one component of the support of $\mathcal{D}$ iff $(B)$ is contained in the singular locus of $S$ ), which is denoted by $\operatorname{Diff}(B)$.

Let $P \subset S$ be a codimension one point of $S$. The following computes the coefficient $p$ of the different $\operatorname{Diff}(0)$ at $P$ :
(16.6.1) If $S$ has two branches at $P$ then $P \notin \operatorname{Supp} B$ and $p=0$. This follows from the more precise result that one of the following holds:
(16.6.1.1) $K+S$ is lt at $P, X$ is smooth at $P$, and $S$ is a normal crossing divisor at $P$.
(16.6.1.2) $K+S$ is lc but not lt at $P$. Then $K+S$ is Cartier at $P$. More precisely, locally analytically at $P, S \subset X$ is isomorphic to $(C \subset T) \times \mathbb{C}^{d-2}$, where $(C \subset T) \cong\left((x y=0) \subset \mathbb{C}^{2} / \mathbb{Z}_{m}\right)$ and $\mathbb{Z}_{m}$ acts with weights $(1, q)$ with $(q, m)=1$.
(16.6.2) If $S$ has one branch at $P$, and $K+S$ is lc but not lt at $P$, then $p=1$.
More precisely $K+S$ has index two at $P$. Let $\pi: X^{\prime} \rightarrow X$ be the index one cover, and $S^{\prime}=\pi^{-1}(S)$. Then $S^{\prime} \subset X^{\prime}$ is as in (16.6.1.2).
(16.6.3) If $S$ has one branch at $P$ and $K+S$ is lt at $P$, then, locally analytically at $P, S \subset X$ is isomorphic to $(C \subset T) \times \mathbb{C}^{d-2}$, where $(C \subset T) \cong$ $\left((x=0) \subset \mathbb{C}^{2} / \mathbb{Z}_{m}\right)$ and $\mathbb{Z}_{m}$ acts with weights $(1, q)$ with $(q, m)=1$. Also, the local class group $\operatorname{Weil}\left(\mathcal{O}_{X, P}\right) \cong \mathbb{Z}_{m}$, and $X$ is smooth at $P$ iff $m=1$. In particular:

$$
p=\frac{m-1}{m}
$$

where $m$ is characterized by any of the following properties:
(16.6.3.1) $m$ is the index of $K+S$ at $P$;
(16.6.3.2) $m$ is the index of $S$ at $P$;
(16.6.3.3) $m$ is the order of the cyclic group Weil $\left(\mathcal{O}_{X, P}\right)$.

Proof. I may assume that $X$ is a surface. All the statements then follow from the classification of log canonical surface singularities in Chapter 3. That $\mathcal{D}$ if $f(B)$ is a Weil divisor also follows from the classification, more specifically from (16.6.1) above. In (16.6.2), it is easy to check that $K_{S^{\prime}}=\left(\pi \mid S^{\prime}\right)^{w}\left(K_{S}+\right.$ $P)$.
16.7 Corollary. Assumptions as in (16.6). Let $B=\sum b_{i} B_{i}$. The coefficient of $[P]$ in $\operatorname{Diff}(B)$ is

$$
\begin{array}{cl}
0 & \text { in case (16.6.1); } \\
1 & \text { in case (16.6.2); } \\
1-\frac{1}{m}+\sum \frac{r_{i} b_{i}}{m} & \text { in case (16.6.3), for suitable } r_{i} \in \mathbb{N}
\end{array}
$$

Proof. In the first two cases $P \notin \operatorname{Supp} B$, so (16.6) applies directly. In the last case the local class group has order $m$. Thus $m B_{i}$ is Cartier at $P$ hence $i^{w}\left(\mathcal{O}_{X}\left(B_{i}\right)\right)=\left(r_{i} / m\right) \mathcal{O}_{S}(P)$ for some $r_{i} \geq 0$.
16.8 Remark. The different is used in the following situation. Let $X$ be a normal variety, and $K_{X}+S+B$ a $\log$ divisor with $S$ reduced and $\llcorner B\lrcorner=0$. Then if $K_{X}+S+B$ is lt, it should be true that $K_{S}+\operatorname{Diff}(B)$ is lt (and conversely) in some suitable sense. Now in general $S$ is a variety with double normal crossings in codimension one and we need to use the appropriate notions of semi log terminal etc. introduced in (12.2).

Unfortunately we encounter the following technical problem:
The birational transform of $S \subset X$ in a $\log$ resolution of $(X, S+B)$ is in general not a semi resolution of $S$ since different components may get separated. Also, the exceptional role of higher normal crossing points complicates the formulation of the result (cf. (16.9.2)). (Recent results of Szabó seem to have settled this problem.)

In dimension three one can overcome some of these problems. The results become somewhat cumbersome, mostly due to our choice of definition of log terminal.
16.9 Proposition. Let $X$ be a normal threefold, $K+S+B$ a log divisor with $S$ reduced. Then:
(16.9.1) If $K+S+B$ is lc then $K_{S}+\operatorname{Diff}(B)$ is slc.
(16.9.2) Let $K+S+B$ be dlt, and $f: Y \rightarrow X$ a good divisorial resolution. Assume that $\llcorner B\lrcorner=\emptyset$. Then, outside a number of triple normal crossing points at which $f$ is an isomorphism, $K_{S}+\operatorname{Diff}(B)$ is semi lt. Moreover, $S$ has a semiresolution without pinch points.
Proof. Let us prove (16.9.2) first. Let $S^{\prime}=f_{*}^{-1}(S)$. Since $K+S+B$ is lc in codimension $2, S$ is semismooth outside a finite set. We have by definition:

$$
\begin{equation*}
K_{Y}+S^{\prime}=f^{*}\left(K_{X}+S+B\right)+\sum a_{i} E_{i} \tag{16.9.3}
\end{equation*}
$$

with all $a_{i}>-1(\llcorner B\lrcorner=0)$. In particular, $f$ is generically an isomorphism above the normal crossing locus of $S$. Also, because $X$ is divisorial lt, no
component of the double curve of $S^{\prime}$ is mapped to a point. All this says that $S^{\prime} \rightarrow S$ is a good semiresolution outside the triple points. By our definitions, $S^{\prime}$ has no pinch points. Note that since $f$ is divisorial, it sends a neighbourhood of the triple normal crossing locus of $S^{\prime}$ isomorphically to a neighbourhood of the triple normal crossing locus of $S$. Now from (16.9.3) and (16.5) we get that

$$
\begin{equation*}
K_{S^{\prime}}=\left(f \mid S^{\prime}\right)^{*}\left(K_{S}+\operatorname{Diff}(B)\right)+\sum a_{i} E_{i} \mid S^{\prime} \tag{16.9.4}
\end{equation*}
$$

We see later in (17.5) that $S$ is $S_{2}$ and seminormal. This however is not important for the rest of the chapter.
(16.9.1) is similar but easier: it is not true that $S^{\prime}$ is a semiresolution of $S$, but this does not affect the slc property (cf. [KSB88, 4.30]).
16.10 Corollary. Let $(x \in X)$ be a three dimensional germ, $S \subset X$ a reduced boundary. If $K_{X}+S$ is divisorial $\log$ terminal and $S$ has at least three components at $x,(x \in S \subset X)$ is analytically isomorphic to $(0 \in$ $\left.(x y z=0) \subset \mathbb{C}^{3}\right)$.

Proof. By (12.2.7) an slt point cannot have three or more components.
16.11 Example. The assumption dlt is necessary in (16.9.2) and (16.10). Indeed, let $S \subset X$ be $(x w=0) \subset\left((x y+z w=0) \subset \mathbb{C}^{4}\right)$. Then $K_{X}+S$ is lt, as can be seen on any of the two standard small resolutions. $K_{X}+S$ however is not dlt. Here $K_{S}=K_{S}+\operatorname{Diff}(0)$ and $S$ has a log canonical quadruple point at the origin.

The rest of the chapter is devoted to the classification of $\log$ terminal singularities $(X, D)$ in dimension three where $\llcorner D\lrcorner$ is "large". These results will not be used later. It gives however a good flavour of how to work with $\log$ terminal singularities and with the different.

The presence of a reduced boundary imposes strong restrictions on log terminal singularities; an example is (16.10). A key tool in classifying terminal and log terminal singularities are standard coverings of various kinds (cf. [CKM88,6.7]):
16.12 Lemma. Let $0 \in X$ be a germ of a normal variety, $D \subset X$ a $\mathbb{Q}$-Cartier integral Weil divisor. There is a cyclic covering $p: X^{\prime} \rightarrow X$, which is uniquely determined by the following properties:
(16.12.1) $p^{*} D=D^{\prime} \subset X^{\prime}$ is a Cartier divisor.
(16.12.2) $p$ is étale in codimension one and is (totally) ramified precisely along the locus where $D$ is not Cartier.
$X^{\prime}$ can also be characterized as the smallest covering of $X$ such that $D^{\prime}$ is Cartier. $X^{\prime}$ is called the index one cover relative to $D$.

To a log divisor $K_{X}+B$ as above one can associate two index one covers $X^{\prime} \rightarrow X$, relatively to $K_{X}+B$ or $B$. It is useful to be able to relate the log terminal property of $X$ and $X^{\prime}$.
16.13 Lemma. Let $X$ be a normal variety, $p: X^{\prime} \rightarrow X$ any finite morphism which is étale in codimension one. Then:
(16.13.1) If $X$ has canonical (terminal) singularities, so does $X^{\prime}$.
(16.13.2) Let $B \subset X$ be a boundary (possibly empty) and let $B^{\prime}=p^{*} B$.
(16.13.2.1) $K_{X}+B$ is lc iff $K_{X^{\prime}}+B^{\prime}$ is lc.
(16.13.2.2) $K_{X}+B$ is plt iff $K_{X^{\prime}}+B^{\prime}$ is plt
(16.13.2.3) If $p$ is a cyclic cover, $X$ is a threefold and $K_{X}+B$ is dlt (resp. $l t$ ), then so is $K_{X^{\prime}}+B^{\prime}$. Furthermore,

$$
\left(B^{\prime} \subset X^{\prime}\right) \cong\left((x y z=0) \subset \mathbb{C}^{3}\right) \quad \Leftrightarrow \quad(B \subset X) \cong\left((x y z=0) \subset \mathbb{C}^{3}\right)
$$

Proof. (16.13.1) is [CKM88, 6.7.(ii)]. (16.13.2.1-2) is proved in (20.3). We only prove (16.13.2.3) for dlt here, the lt case is the same. This also illustrates pretty well the difficulties involved in working with the notion of log terminal.

Let $f: Y \rightarrow X$ be a good divisorial resolution such that $K_{Y}+f_{*}^{-1} B+E=$ $f^{*}\left(K_{X}+B\right)+\sum a_{i} E_{i}$ with all $a_{i}>0$ where $E=\sum E_{i}$ is the $f$-exceptional divisor. Let $Y^{\prime}=\left(Y \times_{X} X^{\prime}\right)^{\nu}$ be the normalized pull back, so that we have a diagram:

Let $E^{\prime}$ be the $f^{\prime}$-exceptional set. The crux of the argument is to be able to construct a good divisorial resolution $\varphi: \tilde{Y} \rightarrow Y^{\prime}$, with the property that the image of the $\varphi$-exceptional locus is entirely contained in $E^{\prime}$. The point is that since $p$ is étale in codimension one, $p^{\prime}$ can only be ramified along $E$, and since $E$ is a normal crossing divisor, $Y^{\prime}$ has toroidal singularities. Set $B^{\prime}=p^{*}(B)$.

Pick a point $q \in f_{*}^{-1} B$. Choose local coordinates $(x, y, z)$ near $q \in Y$ such that the components of $E \cup f_{*}^{-1} B$ are the coordinate planes. Locally, the covering is the normalization of

$$
\left(t^{d}=x^{a} y^{b} z^{c}\right) \subset \mathbb{C}^{1} \times \mathbb{C}^{3}
$$

The local equation of $f_{*}^{-1} B$ is one of the following: $(x y z=0),(x y=0)$, $(x=0)$ or $(1=0)$. In the first case $p^{\prime}$ is unramified along the coordinate planes, thus $a=b=c=0$ and $p^{\prime}$ is étale above $q$. In the second case $p^{\prime}$ is unramified along two of the the coordinate planes, thus $a=b=0$ and $\left(f^{\prime}\right)_{*}^{-1} B^{\prime} \subset Y^{\prime}$ is a (double) normal crossing point. In the third case $p^{\prime}$ is unramified along one of the the coordinate planes, thus $a=0$. Let $T$ be the normalization of the surface singularity $\left(t^{d}=y^{b} z^{c}\right)$. Then

$$
\left[\left(f^{\prime}\right)_{*}^{-1} B^{\prime} \subset Y^{\prime}\right] \cong[T \times\{0\} \subset T \times \mathbb{C}]
$$

Therefore $Y^{\prime}$ is smooth along $\left(f^{\prime}\right)_{*}^{-1} B^{\prime}$, except possibly for some curves $C_{i} \subset Y^{\prime}$ of cyclic quotient singularities that meet $\left(f^{\prime}\right)_{*}^{-1} B^{\prime}$ transversally. We begin constructing a resolution by resolving $Y^{\prime}$ along $C_{i}$. (We care only about a neighborhood of $\left(f^{\prime}\right)_{*}^{-1} B^{\prime}$ in this step.) This gives $\varphi^{\prime}: Y^{\prime \prime} \rightarrow Y^{\prime} . Y^{\prime \prime}$ is smooth in a neighborhood of $\left(\varphi^{\prime}\right)_{*}^{-1}\left(f^{\prime}\right)_{*}^{-1} B^{\prime}$, and $\left(\varphi^{\prime}\right)_{*}^{-1}\left(f^{\prime}\right)_{*}^{-1} B^{\prime}+E^{\prime \prime}$ is a global normal crossing divisor in a neighborhood of $\left(\varphi^{\prime}\right)_{*}^{-1}\left(f^{\prime}\right)_{*}^{-1} B^{\prime}$. It is clear that a good divisorial resolution can now be achieved by blowing up centers contained in $E^{\prime \prime}$ only (and not intersecting $\left.\left(\varphi^{\prime}\right)_{*}^{-1}\left(f^{\prime}\right)_{*}^{-1} B^{\prime}\right)$.

The rest is an easy consequence of the $\log$ ramification formula (20.2). The situation now is the following:

Here $\tilde{f}: \tilde{Y} \rightarrow X^{\prime}$ is a good divisorial resolution, $\tilde{p}$ is generically finite, and $F_{j}$ being any $\tilde{f}$-exceptional component, $\tilde{p}\left(F_{j}\right) \subset E_{i}$ for some $f$-exceptional component $E_{i}$. Write

$$
K_{\tilde{Y}}+\tilde{f}_{*}^{-1} B^{\prime}=\tilde{f}^{*}\left(K_{X^{\prime}}+B^{\prime}\right)+\sum b_{j} F_{j}
$$

Then if $\tilde{p}^{*} E_{i}=\sum_{j} e_{i j} F_{j}$, we have $b_{j}=\sum_{i} e_{i j} a_{i}+r_{j}$ with $r_{j} \geq 0$, by the log ramification formula. Since $\tilde{p}\left(F_{j}\right) \subset E_{i}$ for some $i$, we see that $b_{j}>0$.

Finally, if $f: Y \rightarrow X$ is not the identity then by our construction $\tilde{f}: \tilde{Y} \rightarrow$ $X^{\prime}$ is not the identity, thus $\left(B^{\prime} \subset X^{\prime}\right)$ is different from $\left((x y z=0) \subset \mathbb{C}^{3}\right)$.
16.14 Remark. The converse to (16.13.2.3) is probably also true. Here, however, the problem is to find a suitable resolution of $X$, without blowing up the double locus of $B$. This does not follow directly from Hironaka. (Recently Szabó settled this question.)

From now on $X$ is a threefold, and $B \subset X$ a $\mathbb{Q}$-Cartier reduced boundary such that $K_{X}+B$ is divisorial $\log$ terminal. We begin by classifying these singularities.
16.15 Theorem. Let $x \in B \subset X$ be a three dimensional germ, assume $K+B$ dlt and $B \mathbb{Q}$-Cartier. Then:
(16.15.1) If $B$ has three components, then $x \in B \subset X$ is analytically isomorphic to

$$
0 \in(x y z=0) \subset \mathbb{C}^{3} .
$$

(16.15.2) If $B$ has two components, both of which are $\mathbb{Q}$-Cartier, then $x \in B \subset X$ is analytically isomorphic to

$$
0 \in(x y=0) \subset \mathbb{C}^{3} / \mathbb{Z}_{m}\left(q_{1}, q_{2}, 1\right) \quad \text { where } \quad\left(q_{1}, q_{2}, m\right)=1
$$

(16.15.3) If $B$ has two components, neither of which is $\mathbb{Q}$-Cartier, then $x \in B \subset X$ is analytically isomorphic to

$$
\begin{gathered}
0 \in(z=0) \subset(x y+z f(z, t)=0) \subset \mathbb{C}^{4} / \mathbb{Z}_{m}\left(q_{1},-q_{2}, 1, a\right) \\
\text { where } \quad\left(q_{i}, a, m\right)=\left(q_{1}, q_{2}, m\right)=1
\end{gathered}
$$

Proof. (16.15.1) is a special case of (16.10), so let's prove (16.15.2-3).
Let $p: X^{\prime} \rightarrow X$ be the index one cover relative to $K_{X}+B$, and set $B^{\prime}=p^{*} B$. By (16.13.2.3), $K_{X^{\prime}}+B^{\prime}$ is dlt. Note that $K_{B}+\operatorname{Diff}(0)=$ $K_{B}+\sum \frac{m_{i}-1}{m_{i}} P_{i}$, where $P_{i} \subset B \subset X$ are codimension two singular points on $X$ as in (16.6.3). Also by (16.6.3), $B^{\prime}$ is smooth at $p^{-1}\left(P_{i}\right)$, and $p \mid B^{\prime}$ is ramified in codimension one precisely at $\sum m_{i} P_{i}$. It follows then from (16.13.2.3) that $B^{\prime}$ has two components. Also then $K_{B^{\prime}}=\left(p \mid B^{\prime}\right)^{*}\left(K_{B}+\operatorname{Diff}(0)\right)$ is semi log terminal of index one, by (16.9). Then by [KSB88,4.21] $B^{\prime}=B_{1}^{\prime}+B_{2}^{\prime}$, where $B_{1}^{\prime}$ and $B_{2}^{\prime}$ are smooth and cross normally.

In case (16.15.2), each component of $B^{\prime}$ is $\mathbb{Q}$-Cartier and Cartier in codimension two. It is easy then to show that $X^{\prime}$ must be smooth along $B^{\prime}$. Indeed let $p^{\prime}: X^{\prime \prime} \rightarrow X^{\prime}$ be the index one cover relative to $B_{1}^{\prime}$. Then, since $B_{1}^{\prime}$ is Cartier in codimension two, $p \mid B_{1}^{\prime \prime}: B_{1}^{\prime \prime} \rightarrow B_{1}^{\prime}$ is unramified in codimension one. It follows that $B_{1}^{\prime \prime}$ is regular in codimension one. But $X^{\prime \prime}$ has rational singularities (it is $\log$ terminal), hence CM , so $B_{1}^{\prime \prime}$ is also CM , and normal by the Serre criterion. But then $p \mid B_{1}^{\prime \prime}: B_{1}^{\prime \prime} \rightarrow B_{1}^{\prime}$ is a split cover, since it is unramified in codimension one and $B_{1}^{\prime}$ is smooth. This means that $p^{\prime}=\mathrm{id}$, and since $B_{1}^{\prime}$ is smooth and Cartier, $X^{\prime}$ is smooth. Now (16.15.2) follows at once: $B^{\prime} \subset X^{\prime} \cong(x y=0) \subset \mathbb{C}^{3}$, and $x \in B \subset X$ is analytically isomorphic to $0 \in(x y=0) \subset \mathbb{C}^{3} / \mathbb{Z}_{m}\left(q_{1}, q_{2}, q_{3}\right)$. We may assume $q_{3}=1$, because $p$ is unramified along $B_{1} \cap B_{2}$, and ( $\left.q_{1}, q_{2}, m\right)=1$ because $p$ is unramified in codimension one.

In case (16.15.3), let $p^{\prime}: X^{\prime \prime} \rightarrow X^{\prime}$ be the index one cover relative to $B^{\prime}$. Then it is clear that, as for $B^{\prime}, B^{\prime \prime}=B_{1}^{\prime \prime}+B_{2}^{\prime \prime}$, where $B_{1}^{\prime \prime}$ and $B_{2}^{\prime \prime}$ are smooth and cross normally. Then, $p^{\prime} \mid B^{\prime \prime}: B^{\prime \prime} \rightarrow B^{\prime}$ is a split covering, since it is unramified in codimension one. It follows that $p^{\prime}=\mathrm{id}$ and $B^{\prime}$ is also Cartier. Then $X^{\prime}$ has cDV singularities and the result follows at once.
16.16 Remark. It should be possible to check directly (although I did not do it) that the singularities in (16.15.2-3) are dlt.

If $B$ has only one component, it is not possible to give a compact description as above. Even if $B$ is Cartier, we know from inversion of adjunction (16.9) that any $\mathbb{Q}$-Gorenstein deformation (in particular the trivial deformation) of a surface quotient singularity is log terminal. However, under further restrictions, it is possible to come up with a short list:
16.17 Proposition. [KSB88] Let $x \in B \subset X$ be a three dimensional germ, assume $K+B$ is dlt and $B$ is Cartier. Also assume that $X$ is $c D V$ outside $B$. Then $x \in B \subset X$ is analytically isomorphic to one of the following:
(16.17.1) $0 \in(x y z=0) \subset \mathbb{C}^{3}$;
(16.17.2) $0 \in(t=0) \subset\left(x^{2}+f(y, z, t)=0\right) \subset \mathbb{C}^{4}$ where $\left(x^{2}+f(y, z, 0)=0\right)$ defines a Du Val singularity;
(16.17.3) $0 \in(t=0) \subset\left(x y+f\left(z^{r}, t\right)=0\right) \subset \mathbb{C}^{3} / \mathbb{Z}_{r}(a,-a, 1,0)$.

# 17. ADJUNCTION AND DISCREPANCIES 

JÁnos Kollár

The aim of this chapter is to investigate the problem posed in Chapter 16 of comparing the discrepancies of $(X, S+B)$ and $(S, \operatorname{Diff}(B))$. Before formulating the first result, we need to define some other variants of discrep $(X)$.
17.1 Definition. Let $X$ be a normal scheme, $D=\sum d_{i} D_{i}$ a boundary and let $Z \subset S \subset X$ be closed subschemes. (More generally, we may allow $X$ to be nonnormal as long as the conditions of (2.6) are satisfied.) We use the following refinements of (1.6):

```
discrep \((X, D)\)
    \(=\inf _{E}\left\{a(E, X, D) \mid E\right.\) is exceptional, \(\left.\emptyset \neq \operatorname{Center}_{X}(E)\right\} ;\)
discrep \((\) Center \(\subset Z, X, D)\)
    \(=\inf _{E}\left\{a(E, X, D) \mid E\right.\) is exceptional, \(\left.\emptyset \neq \operatorname{Center}_{X}(E) \subset Z\right\} ;\)
\(\operatorname{discrep}(S \cap\) Center \(\subset Z, X, D)\)
    \(=\inf _{E}\left\{a(E, X, D) \mid E\right.\) is exceptional, \(\left.\emptyset \neq S \cap \operatorname{Center}_{X}(E) \subset Z\right\} ;\)
```

One can also define versions where we allow $E$ to be nonexceptional as well. These are denoted by totaldiscrep. Of course, totaldiscrep $=$ discrep if $Z$ has codimension at least two. We write discrep $(S \cap \operatorname{Center} \neq \emptyset, X, D)$ instead of $\operatorname{discrep}(S \cap$ Center $\subset S, X, D)$ which is misleading in appearance.
17.1.1 Proposition. (17.1.1.1) Any of the discrepancies defined above is either $-\infty$ or $\geq-1$ and the infimum is a minimum.
(17.1.1.2) For any $Z \subset S \subset X$

$$
\begin{aligned}
\operatorname{discrep}(\text { Center } \subset Z, X, D) & \geq \operatorname{discrep}(S \cap \text { Center } \subset Z, X, D) \\
& \geq \operatorname{totaldiscrep}(X, D) ;
\end{aligned}
$$

(17.1.1.3) If discrep $($ Center $\subset Z, X, D) \geq-1$ then there is an open neighborhood $Z \subset U \subset X$ such that totaldiscrep $(U, D) \geq-1$.

Proof. (17.1.1.2) is clear from the definition.
In order to see the other two claims, take a log resolution $f: Y \rightarrow(X, D)$. If $a(E, X, D) \geq-1$ for every divisor $E \subset Y$ then

$$
\text { totaldiscrep }(X, D)=\min _{E}\{a(E, X, D) \mid E \subset Y\}
$$

by (4.12.1.2). Similarly, (4.12.1.1) implies (17.1.1.1) for the other versions.
Assume now that there is a divisor $E \subset X$ such that $a(E, X, D)=-1-c$ for some $c>0$. Let $p \in E$ be any point. Choose a general codimension one subvariety $p \in W \subset E$. Let $g_{1}: Y_{1} \rightarrow Y$ be the blow up of $W$ and let $E_{1} \subset Y_{1}$ be the exceptional divisor. If $g_{i}: Y_{i} \rightarrow Y$ and $E_{i} \subset Y_{i}$ are already defined then let $g_{i+1}: Y_{i+1} \rightarrow Y_{i} \rightarrow Y$ be the blow up of $E_{i} \cap\left(g_{i}\right)_{*}^{-1}(E)$ and let $E_{i+1}$ be the exceptional divisor of $Y_{i+1} \rightarrow Y_{i}$. By an easy computation $a\left(E_{j}, X, D\right)=-j c$. Let $p_{j} \in E_{j}$ be a point such that $g_{j}\left(p_{j}\right)=p$ and let $F_{j}$ be the divisor obtained by blowing up $p_{j}$. Then

$$
a\left(F_{j}, X, D\right) \leq-j c+\text { const. hence } \quad \text { discrep }(\text { Center } \subset f(p), X, D)=-\infty
$$

Choosing $p$ such that $f(p) \in Z$ completes the proof.
An upper bound is harder to find:
17.1.2 Conjecture. [Shokurov88] Let $0 \in(X, D)$ be an n-dimensional normal singularity. Assume that $K_{X}+D$ is $\mathbb{Q}$-Cartier. Then

$$
\operatorname{discrep}(\text { Center } \subset 0, X, D) \leq \operatorname{dim} X-1
$$

and equality holds only if $X$ is smooth and $0 \notin D$. (cf. (1.8)).
17.1.3 Remark. Assume that the conjecture fails for $0 \in X$. Then $(X, D)$ is terminal. Thus if a list of terminal singularities is known, the conjecture can be verified. Therefore (17.1.2) is trivial if $\operatorname{dim} X \leq 2$. For $\operatorname{dim} X=3$ it was checked by Markushevich (unpublished).

The following is the easy direction in comparing discrepancies:
17.2 Theorem. Let $X$ be a variety and let $S+B$ be a Weil divisor. Assume that $S$ is reduced and $K+S+B$ is lc in codimension two. Assume furthermore that $K+S+B$ is $\mathbb{Q}$-Cartier. Let $Z \subset S$ be a closed subscheme. Then (17.2.1)
totaldiscrep $($ Center $\subset Z, S, \operatorname{Diff}(B)) \geq \operatorname{discrep}($ Center $\subset Z, X, S+B)$
$\geq \operatorname{discrep}(S \cap$ Center $\subset Z, X, S+B)$.

In particular,

$$
\begin{equation*}
\text { totaldiscrep }(S, \operatorname{Diff}(B)) \geq \operatorname{discrep}(X, S+B) \tag{17.2.2}
\end{equation*}
$$

Proof. Set $Z=S$ in (17.2.1) to obtain (17.2.2). Also, the second inequality of (17.2.1) is obvious. For the rest we need a simple lemma which we state in a general setup:
17.2.3 Lemma. Let $f: Y \rightarrow X$ be a proper birational morphism with exceptional divisors $E_{j}$. Assume that $Y$ is normal. Let $S+B$ be a $\mathbb{Q}$-divisor on $X$ and let $S^{\prime}$ be the birational transform of $S$ on $Y$. Assume that $(X, S)$ and $\left(Y, S^{\prime}\right)$ are lc in codimension two. Let $D \subset S$ be the union of all codimension one points of $S$ above which $S^{\prime} \rightarrow S$ is not an isomorphism and let $D^{\prime} \subset S^{\prime}$ be the preimage of $D$. Finally let

$$
K_{Y}+f_{*}^{-1}(S+B) \equiv f^{*}\left(K_{X}+S+B\right)+\sum a\left(E_{j}, S+B\right) E_{j}
$$

Then
(17.2.4)

$$
\begin{aligned}
\left(f \mid S^{\prime}\right)_{*} \operatorname{Diff}_{S^{\prime}}\left(f_{*}^{-1} B-\sum a\left(E_{j}, S+B\right) E_{j}\right) & =\operatorname{Diff}_{S}(B)+2[D] ; \quad \text { and } \\
K_{S^{\prime}}+\operatorname{Diff}_{S^{\prime}}\left(f_{*}^{-1} B-\sum a\left(E_{j}, S+B\right) E_{j}\right) & \equiv\left(f \mid S^{\prime}\right)^{*}\left(K_{S}+\operatorname{Diff}_{S}(B)\right)
\end{aligned}
$$

Proof. The left hand side of the second eqality is $f^{*}(K+S+B) \mid S^{\prime}$ and the right hand side is $f^{*}(K+S+B \mid S)$. Thus the second equality is clear.

The first is a codimension one question on $S$, so that by shrinking $X$, we may assume that $S$ is semismooth and $f: S^{\prime} \rightarrow S$ is finite. Assume that $m\left(K_{X}+S+B\right)$ is Cartier. Then

$$
\begin{aligned}
m K_{S^{\prime}} & +m\left(f \mid S^{\prime}\right)_{*}^{-1}(\operatorname{Diff}(B))+m D^{\prime} \\
& =\left(f \mid S^{\prime}\right)^{*}\left(m\left(K_{S}+\operatorname{Diff}(B)\right)\right) \\
& =f^{*}\left(m\left(K_{X}+S+B\right) \mid S^{\prime}\right) \\
& =m K_{S^{\prime}}+m \operatorname{Diff}_{S^{\prime}}\left(f_{*}^{-1} B-\sum a\left(E_{j}, S+B\right) E_{j}\right)
\end{aligned}
$$

where all the equalities are equalities of divisors. Pushing this down to $S$ gives the first equality.

In order to see (17.2) let $f: Y \rightarrow X$ be a log resolution of $(X, S+B)$ with exceptional divisors $E_{j}$. Let $E_{j} \cap S^{\prime}=\sum C_{j k}+\sum D_{j k}$ where the $C_{j k}$ are the $\left(f \mid S^{\prime}\right)$-exceptional components of the intersection and $f \mid D_{j k}$ is birational. For simplicity assume that $S^{\prime}$ is disjoint from $f_{*}^{-1}(B)$.

Restricting (17.2.4) to $S^{\prime}$ we obtain:

$$
\begin{aligned}
K_{S^{\prime}} & +\left(f \mid S^{\prime}\right)_{*}^{-1}(\operatorname{Diff}(B))+D^{\prime} \\
& \equiv f^{*}\left(K_{S}+\operatorname{Diff}(B)\right)+\sum_{j, k} a\left(E_{j}, S+B\right) C_{j k}
\end{aligned}
$$

Therefore

$$
\begin{align*}
& a\left(C_{j k}, S, \operatorname{Diff}(B)\right)=a\left(E_{j}, X, S+B\right), \quad \text { and } \\
& a\left(D_{j k}, S, \operatorname{Diff}(B)\right)=a\left(E_{j}, X, S+B\right) . \tag{17.2.5}
\end{align*}
$$

Every exceptional divisor over $S$ appears as an irreducible component of $E_{j} \cap S^{\prime}$ for a suitable choice of $f$. The only problem is that $f\left(C_{j k}\right) \subset Z$ does not imply $f\left(E_{j}\right) \subset Z$. However if we blow up $C_{j k}$ then we obtain a new exceptional divisor $E_{j k}$ such that

$$
f\left(E_{j k}\right)=f\left(C_{j k}\right) \subset Z \quad \text { and } \quad a\left(E_{j k}, X, S+B\right)=a\left(E_{j}, X, S+B\right) .
$$

This proves (17.2.1).
The following conjecture asserts that the inequalities in (17.2) are equalities. Special cases were discussed earlier in [KSB88,Chapter 6; Stevens88; Shokurov91,3.3]. The conjecture (or similar results and conjectures) will be frequently referred to as adjunction (if we assume something about $X$ and obtain conclusions about $S$ ) or inversion of adjunction (if we assume something about $S$ and obtain conclusions about $X$ ).
17.3 Conjecture. Notation as in (17.2). Then
(17.3.1)

$$
\begin{aligned}
\text { totaldiscrep }(\text { Center } \subset Z, S, \operatorname{Diff}(B)) & =\operatorname{discrep}(\text { Center } \subset Z, X, S+B) \\
& =\operatorname{discrep}(S \cap \operatorname{Center} \subset Z, X, S+B)
\end{aligned}
$$

In particular,
(17.3.2) $\quad$ totaldiscrep $(S, \operatorname{Diff}(B))=\operatorname{discrep}(\operatorname{Center} \cap S \neq \emptyset, X, S+B)$.

Unfortunately, I do not know how to prove these in full generality. The rest of the chapter is devoted to proving some important special cases.

The following technical result is crucial in (17.6-7). It was proved by [Shokurov91,5.7] for surfaces.
17.4 Theorem. Let $X, Z$ be normal varieties (or analytic spaces) and let $h: X \rightarrow Z$ be a proper morphism with connected fibers. Let $D=\sum d_{i} D_{i}$ be a $\mathbb{Q}$-divisor on $X$. Assume that
(17.4.1) if $d_{i}<0$ then $h\left(D_{i}\right)$ has codimension at least two in $Z$; and
(17.4.2) $-\left(K_{X}+D\right)$ is $h$-nef and $h$-big. (If $h$ is birational then $h$-big is automatic.)

Let

$$
f: Y \xrightarrow{g} X \xrightarrow{h} Z
$$

be a resolution of singularities such that $\operatorname{Supp} g^{-1}(D)$ is a divisor with normal crossings. Let

$$
K_{Y}=g^{*}\left(K_{X}+D\right)+\sum e_{i} E_{i}
$$

Further let

$$
A=\sum_{i: e_{i}>-1} e_{i} E_{i} \quad \text { and } \quad F=-\sum_{i: e_{i} \leq-1} e_{i} E_{i}
$$

Then $\operatorname{Supp} F=\operatorname{Supp}\llcorner F\lrcorner$ is connected in a neighborhood of any fiber of $f$. Proof. By definition

$$
\ulcorner A\urcorner-\llcorner F\lrcorner=K_{Y}+\left(-g^{*}\left(K_{X}+D\right)\right)+\{-A\}+\{F\},
$$

and therefore by [KMM87,1-2-3]

$$
R^{1} f_{*} \mathcal{O}_{Y}(\ulcorner A\urcorner-\llcorner F\lrcorner)=0
$$

Applying $f_{*}$ to the exact sequence

$$
0 \rightarrow \mathcal{O}_{Y}(\ulcorner A\urcorner-\llcorner F\lrcorner) \rightarrow \mathcal{O}_{Y}(\ulcorner A\urcorner) \rightarrow \mathcal{O}_{\llcorner F\lrcorner}(\ulcorner A\urcorner) \rightarrow 0
$$

we obtain that

$$
\begin{equation*}
f_{*} \mathcal{O}_{Y}(\ulcorner A\urcorner) \rightarrow f_{*} \mathcal{O}_{\llcorner F\lrcorner}(\ulcorner A\urcorner) \tag{17.4.3}
\end{equation*}
$$

is surjective. Let $E_{i}$ be an irreducible component of $\ulcorner A\urcorner$. Then either $E_{i}$ is $g$-exceptional or $E_{i}$ is the birational transform of some $D_{i}$ and $d_{i}=-e_{i}<0$.

Thus $g_{*}(\ulcorner A\urcorner)$ is $h$-exceptional and

$$
f_{*} \mathcal{O}_{Y}(\ulcorner A\urcorner)=h_{*}\left(\mathcal{O}_{X}\left(g_{*}(\ulcorner A\urcorner)\right)\right)=\mathcal{O}_{Z}
$$

Assume that $\llcorner F\lrcorner$ has at least two connected components $\llcorner F\lrcorner=F_{1} \cup F_{2}$ in a neighborhood of $f^{-1}(z)$ for some $z \in Z$. Then

$$
f_{*} \mathcal{O}_{\llcorner F\lrcorner}(\ulcorner A\urcorner)_{(z)} \cong f_{*} \mathcal{O}_{F_{1}}(\ulcorner A\urcorner)_{(z)}+f_{*} \mathcal{O}_{F_{2}}(\ulcorner A\urcorner)_{(z)},
$$

and neither of these summands is zero. Thus $f_{*} \mathcal{O}_{\llcorner F\lrcorner}(\ulcorner A\urcorner)_{(z)}$ cannot be the quotient of the cyclic module $\mathcal{O}_{z, Z} \cong f_{*} \mathcal{O}_{Y}(\ulcorner A\urcorner)_{(z)}$.
17.5 Corollary. If $(X, D)$ is lt then $\llcorner D\lrcorner$ is seminormal and it has a semiresolution with normal crossing points only. If ( $X, D$ ) is dlt then $\llcorner D\lrcorner$ is seminormal and $S_{2}$. If ( $X, D$ ) is dlt and every irreducible component of $\llcorner D\lrcorner$ is $\mathbb{Q}$-Cartier then every irreducible component of $\llcorner D\lrcorner$ is normal.
Proof. We apply (17.4) to $h: X \cong Z$. Let $g: Y \rightarrow X$ be a $\log$ resolution. Then $F=\llcorner F\lrcorner$ is the birational transform of $\llcorner D\lrcorner$. By assumption $F$ has only normal crossing points. In particular, $F$ is seminormal and $S_{2}$. We can successively blow up the normal crossing points of multiplicity at least 3 starting with the highest multiplicity locus to obtain a semiresolution of $\llcorner D\lrcorner$ with normal crossing points only.

By (17.4.3) the composite

$$
g_{*} \mathcal{O}_{Y}(\ulcorner A\urcorner) \cong \mathcal{O}_{X} \rightarrow \mathcal{O}_{\llcorner D\lrcorner} \hookrightarrow g_{*} \mathcal{O}_{F} \hookrightarrow g_{*} \mathcal{O}_{F}(\ulcorner A\urcorner)
$$

is surjective, and hence

$$
\begin{equation*}
\mathcal{O}_{\llcorner D\lrcorner} \cong g_{*} \mathcal{O}_{\llcorner F\lrcorner} \tag{17.5.1}
\end{equation*}
$$

Let $n: B \rightarrow\llcorner D\lrcorner$ be the seminormalizsation of $\llcorner D\lrcorner$. Then $B \times{ }_{n} F \rightarrow F$ is a homeomorphism, thus an isomorphism. Therefore $F \rightarrow\llcorner D\lrcorner$ factors through $n$. Thus by (17.5.1) $n_{*} \mathcal{O}_{B}=\mathcal{O}_{\llcorner D\lrcorner}$, hence $n$ is an isomorphism.

Assume now that $(X, D)$ is dlt. Let $Z \subset\llcorner D\lrcorner$ be a closed subset of codimension $\geq 2$. I claim that $Z^{\prime}=\operatorname{Sing} F \cap g^{-1}(Z)$ has codimension $\geq 2$ in $F$. Assume the contrary. Then there is an irreducible component $Z^{\prime \prime} \subset Z^{\prime}$ such that $Z^{\prime \prime} \subset Y$ has codimension two and it is contained in the exceptional set of $g$. Therefore $Z^{\prime \prime}$ is contained in an exceptional divisor $E$ of $g$. Since Supp $g^{-1}(D)$ is a normal crossing divisor, there is at most one irreducible component of $F$ containing $Z^{\prime \prime}$. This contradicts $Z^{\prime \prime} \subset \operatorname{Sing} F$.

Let $n^{\prime}: B^{\prime} \rightarrow\llcorner D\lrcorner$ be the $S_{2}$-ization of $\llcorner D\lrcorner$ [EGA, IV.5.10.16-17]. Then $B^{\prime} \times_{n^{\prime}} F \rightarrow F$ is finite and birational on every irreducible component. Furthermore, by the above considerations, it is a homeomorphism in codimension one. Since $F$ is seminormal and $S_{2}$, this implies that it is an isomorphism. Therefore $F \rightarrow\llcorner D\lrcorner$ factors through $n^{\prime}$. Thus by (17.5.1) $n_{*}^{\prime} \mathcal{O}_{B^{\prime}}=\mathcal{O}_{\llcorner D\lrcorner}$, hence $n^{\prime}$ is an isomorphism.

Assume that every irreducible component of $\llcorner D\lrcorner$ is $\mathbb{Q}$-Cartier and let $D_{1} \subset$ $\llcorner D\lrcorner$ be an irreducible component. We can replace $D$ by $D^{\prime}=D-(1 / 2)(\llcorner D\lrcorner-$ $D_{1}$ ). Then ( $X, D^{\prime}$ ) is dlt and $\left\llcorner D^{\prime}\right\lrcorner=D_{1}$. Thus $D_{1}$ is seminormal and $S_{2}$. By the classification of Chapter 3, it is also smooth in codimension one, hence normal.
17.5.2 Example. (cf. (16.11)) Let $X=(x y-u v=0) \subset \mathbb{C}^{4}$ and

$$
D=(x=u=0)+(y=v=0)+\frac{1}{2} \sum_{i=1}^{4}\left(x+2^{i} u=y+2^{-i} v=0\right) .
$$

Then $(X, D)$ is lt and $\llcorner D\lrcorner$ is two planes intersecting at a single point. Thus it is not $S_{2}$.

The most important application of the above connectedness result is to the problem of inversion of adjunction. The following theorem shows that in the notation of (17.3)
totaldiscrep $(S, \operatorname{Diff}(B))>-1 \quad \Leftrightarrow \quad \operatorname{discrep}($ Center $\cap S \neq \emptyset, X, S+B)>-1$.
17.6 Theorem. Let $X$ be normal and let $S \subset X$ be an irreducible divisor. Let $B$ be an effective $\mathbb{Q}$-divisor such that $\llcorner B\lrcorner=\emptyset$ and assume that $K_{X}+S+B$ is $\mathbb{Q}$-Cartier. Then $K_{X}+S+B$ is plt in a neighborhood of $S$ iff $K_{S}+\operatorname{Diff}(B)$ is klt.

Proof. Let $g: Y \rightarrow X$ be a resolution of singularities and as in (17.4) let

$$
K_{Y}=g^{*}\left(K_{X}+S+B\right)+A-F
$$

Let $S^{\prime} \subset Y$ be the birational transform of $S$ and let $F=S^{\prime} \cup F^{\prime}$. By adjunction

$$
K_{S^{\prime}}=g^{*}\left(K_{S}+\operatorname{Diff}(B)\right)+\left(A-F^{\prime}\right) \mid S^{\prime}
$$

$K_{X}+S+B$ is plt iff $F^{\prime}=\emptyset$ and $K_{S}+$ Diff $B$ is plt iff $F^{\prime} \cap S^{\prime}=\emptyset$. Let $h: X \rightarrow X$ be the identity. By (17.4) $S^{\prime} \cup F^{\prime}$ is connected, hence $F^{\prime}=\emptyset$ iff $F^{\prime} \cap S^{\prime}=\emptyset$.
17.7 Theorem. Let $X$ be normal and let $S \subset X$ be an irreducible divisor. Let $B$ and $B^{\prime}$ be effective $\mathbb{Q}$-divisors such that $\llcorner B\lrcorner=\emptyset$. Assume furthermore that
(17.7.1) $B^{\prime}$ is $\mathbb{Q}$-Cartier, $K_{X}+S+B$ is $\mathbb{Q}$-Cartier, and
(17.7.2) $K_{X}+S+B$ is plt.

Then $K_{X}+S+B+B^{\prime}$ is lc in a neighborhood of $S$ iff $K_{S}+\operatorname{Diff}\left(B+B^{\prime}\right)$ is lc.

Proof. By (2.17.5) $K_{X}+S+B+B^{\prime}$ (resp. $K_{S}+\operatorname{Diff}\left(B+B^{\prime}\right)$ ) is lc iff $K_{X}+S+B+t B^{\prime}\left(\right.$ resp. $\left.K_{S}+\operatorname{Diff}\left(B+t B^{\prime}\right)\right)$ is plt for every $0 \leq t<1$. Thus (17.6) implies (17.7).

The following corollary is very important in Chapter 18. (See (18.3) for the definition of maximally lc.)
17.8 Corollary. Let $X$ be normal, $\mathbb{Q}$-factorial and let $S \subset X$ be an irreducible divisor. Let $\sum d_{i} D_{i}$ be an effective $\mathbb{Q}$-divisor. Assume that $K_{X}+S$ is plt. Set

$$
\Delta=\operatorname{Diff}_{S}(0) \quad \text { and } \quad B_{i}=i^{w} \mathcal{O}_{X}\left(D_{i}\right)
$$

where $i: S \rightarrow X$ is the natural injection and $i^{w}$ is defined in (16.3.6).
Then $K_{X}+S+\sum d_{i} D_{i}$ is maximally lc near a point $x \in S$ iff $K_{S}+\Delta+$ $\sum d_{i} B_{i}$ is maximally lc near $x \in S$.

The rest of the chapter is devoted to showing that if the minimal model program works in dimension $n$ then (17.3) holds for small discrepancies for $\operatorname{dim} X=n$. The precise assumptions are the following.
17.9 Assumption. For the rest of the chapter we use the following special case of the Log Minimal Model Program:
$\left(*_{n}\right)$. Let $f: Y \rightarrow X$ be a proper birational morphism. Assume that $Y$ is normal, $\mathbb{Q}$-factorial and $\operatorname{dim} Y \leq n$. Let $D$ be a $\mathbb{Q}$-Weil divisor on $Y$ such that $(Y, D)$ is $\log$ terminal. Then the steps of the $\left(K_{Y}+D\right)$-MMP (as described in $(2.26)$ ) all exist and the process terminates with a relative minimal model $\bar{f}:(\bar{Y}, \bar{D}) \rightarrow X$.

We know that $\left(*_{2}\right)$ and $\left(*_{3}\right)$ hold.
We start with the following result which is of considerable interest in itself. It is a generalisation of (6.9.4).
17.10 Theorem. Assume $\left(*_{n}\right)$. Let $(X, B)$ be a $\log$ canonical pair, $\operatorname{dim} X \leq$ $n$. Let $f: Y \rightarrow X$ be a $\log$ resolution. Let $\mathcal{E}$ be a subset of the exceptional divisors $\left\{E_{i}\right\}$ such that
(17.10.1.1) If $a\left(E_{i}, B\right)=-1$ then $E_{i} \subset \mathcal{E}$;
(17.10.1.2) If $E_{j} \subset \mathcal{E}$ then $a\left(E_{j}, B\right) \leq 0$.

Then there is a factorization

$$
f: Y \xrightarrow{h} X(\mathcal{E}) \xrightarrow{g} X
$$

with the following properties:
(17.10.2.1) $h$ is a local isomorphism at every generic point of $\mathcal{E}$;
(17.10.2.2) $h$ contracts every exceptional divisor not in $\mathcal{E}$;

$$
\begin{align*}
& h_{*}\left(K_{Y}+f_{*}^{-1}(B)+\sum-a\left(E_{i}, B\right) E_{i}\right) \\
& \quad=K_{X(\mathcal{E})}+g_{*}^{-1}(B)+\sum_{E_{i} \subset \mathcal{E}}-a\left(E_{i}, B\right) h_{*}\left(E_{i}\right)  \tag{17.10.2.3}\\
& \quad \equiv g^{*}\left(K_{X}+B\right) \quad \text { is } \log \text { terminal. }
\end{align*}
$$

Proof. For a small $\epsilon$ let

$$
d\left(E_{i}\right)= \begin{cases}-a\left(E_{i}, B\right) & \text { if } \quad E_{i} \subset \mathcal{E}  \tag{17.10.3}\\ \max \left\{-a\left(E_{i}, B\right)+\epsilon, 0\right\} & \text { if } \quad E_{i} \not \subset \mathcal{E}\end{cases}
$$

Then

$$
K_{Y}+f_{*}^{-1}(B)+\sum d\left(E_{i}\right) E_{i} \equiv f^{*}\left(K_{X}+B\right)+\sum_{E_{j} \notin \mathcal{E}}\left(d_{j}+a\left(E_{j}, B\right)\right) E_{j} .
$$

Apply the $\left(K_{Y}+f_{*}^{-1}(B)+\sum d\left(E_{i}\right) E_{i}\right)$-MMP to $Y / X$. Every extremal ray is supported in (the birational transform of) $h_{*}(\mathcal{E})$. Also, an effective exceptional divisor is never nef. Thus the MMP stops with a factorization

$$
f: Y \xrightarrow{h} X(\mathcal{E}) \xrightarrow{g} X
$$

such that $h_{*}(\mathcal{E})=\emptyset$ and $h$ is an isomorphism at every generic point of $\mathcal{E}$.
17.11 Corollary. Assume ( $*_{n}$ ). Let $(X, S+B)$ be as in (17.2) such that $\operatorname{dim} X \leq n$ and $X$ is $\mathbb{Q}$-factorial. Assume furthermore that either,
(17.11.1) $(X, S+B)$ is plt and $d=\operatorname{discrep}(S \cap$ Center $\subset Z, X, S+B) \leq 0$; or
(17.11.2) $(X, S+B)$ is $l c$ and $d=-1$.

Then the equalities (17.3.1) hold.
Proof. Let $f: Y \rightarrow X$ be a $\log$ resolution of $(X, S+B)$ such that $f^{-1}(Z)$ is a divisor with normal crossings. Let $S^{\prime \prime} \subset Y$ be the birational transform of $S$.

Let $\mathcal{E}$ be the set of exceptional divisors with discrepancy $d$ such that $S \cap$ $\operatorname{Center}_{X}(E) \subset Z$. By assumption $\mathcal{E} \neq \emptyset$. We apply the

$$
\left(K_{Y}+f_{*}^{-1}(S+B)+\sum d\left(E_{i}\right) E_{i}\right) \text {-MMP on } f: Y \rightarrow X .
$$

At the end we obtain $h: Y \rightarrow X(\mathcal{E})$ and $g: X(\mathcal{E}) \rightarrow X$ such that

$$
h_{*}\left(K_{Y}+f_{*}^{-1}(S+B)+\sum d\left(E_{i}\right) E_{i}\right)=g^{*}(K+S+B) .
$$

Let $S^{\prime} \subset X(\mathcal{E})$ be the birational transform of $S$. Since $X$ is $\mathbb{Q}$-factorial, the exceptional set of $g$ is exactly $h_{*}(\mathcal{E})$, hence $S^{\prime}$ intersects the exceptional divisor $h_{*}(\mathcal{E})$. $f\left(S^{\prime}\right) \cap f\left(h_{*}(\mathcal{E})\right) \subset Z$, hence every irreducible component $C \subset S^{\prime} \cap h_{*}(\mathcal{E})$ lies above $Z$.

By (16.7) the coefficient $p(C)$ of $[C]$ in $\operatorname{Diff}\left(g_{*}^{-1} B-d h_{*}(\mathcal{E})\right)$ is

$$
p(C)=1-\frac{1}{m}+\sum \frac{r_{i} b_{i}}{m}+\frac{r_{0}(-d)}{m} \geq 1-\frac{1+d}{m} \geq-d,
$$

and by (17.2.3) $a(C, S, \operatorname{Diff}(B))=-p(C)$. Combining with (17.2) we are done.
17.12 Corollary. Assume $\left(*_{n}\right)$. Let $(X, S+B)$ be as in (17.2) such that $\operatorname{dim} X \leq n$ and $X$ is $\mathbb{Q}$-factorial. Then

$$
\operatorname{totaldiscrep}(S, \operatorname{Diff}(B))=\operatorname{discrep}(\text { Center } \cap S \neq \emptyset, X, S+B)
$$

Proof. Let $d=\operatorname{discrep}$ (Center $\cap S \neq \emptyset, X, S+B$ ). By blowing up a codimension one smooth point of $S$ we see that $d \leq 0$. If $d>-1$ then $(X, S+B)$ is plt, thus (17.11.1) implies the required equality.

If $d=-1$ then we can apply (17.11.2).
Finally assume that $d=-\infty$. We need to show that $(S, \operatorname{Diff}(B))$ cannot be lc. Let $f:\left(Y, f_{*}^{-1}(S+B)+E\right) \rightarrow X$ be a log terminal model of $(X, S+B)$ where $E$ is the reduced exceptional divisor. Write

$$
K_{Y}+f_{*}^{-1}(S+B)+E \equiv f^{*}\left(K_{X}+S+B\right)-F
$$

where by (2.19) $F$ is effective and either $F=0$ or $\operatorname{Supp} F=\operatorname{Supp} E$. In the former case $(X, S+B)$ is lc. In the latter case let $S^{\prime} \subset Y$ denote the birational transform of $S$. Then $S^{\prime}$ and $E$ intersect nontrivially and

$$
K_{S^{\prime}}+\operatorname{Diff}_{S^{\prime}}\left(f_{*}^{-1}(B)+E+F\right)=f^{*}\left(K_{S}+\operatorname{Diff}_{S}(B)\right)
$$

contains a component with coefficient greater than 1 by (16.7).
Thus $(S, \operatorname{Diff}(B))$ is not lc.

# 18. REDUCTION TO SPECIAL FLIPS 

Antonella Grassi and János Kollár

18.1 Conventions. In this chapter $f:(X, K+S+B) \rightarrow Z$ denotes a small contraction such that $-(K+S+B)$ is $f$-ample. We always assume that $K+S+B$ is $\log$ canonical, $S$ is reduced and $B=\sum_{1}^{n} b_{i} B_{i}$ with $0<b_{i} \leq 1$ where the $B_{i}$ are distinct, irreducible and reduced. (In general $B$ is allowed to have a reduced part.) The assumptions imply that $S$ and $B$ have no irreducible components in common. One should keep in mind that the sum $S+B$ does not determine $S$ and $B$ uniquely. Irreducible components with coefficient 1 can be either in $S$ or in $B$.

Let $0 \in Z$ be a distinguished point and set $C=f^{-1}(0)$. In dimension three $C$ is the whole exceptional set (after possibly shrinking $Z$ ) but not necessarily so in higher dimensions. Any irreducible curve in $C$ is called a fipping curve.

We always assume that every irreducible component of $S+B$ intersects $C$.

### 18.2 Definition.

(18.2.1) The type of $S+B$ is the sequence $\left(b_{1}, \cdots, b_{n}\right)$. It is denoted by type $(S+B)$. We usually do not think of $B$ with a specified ordering of the components in mind, so strictly speaking $f$ has several types.
(18.2.2) We introduce an ordering on sequences of numbers as follows:
$\left(b_{1}^{s}, \cdots, b_{m}^{s}\right)<\left(b_{1}^{t}, \cdots, b_{n}^{t}\right)$ if either $n<m$ or $n=m$ and $b_{i}^{s} \leq b_{i}^{t} \forall i$, with strict inequality holding for at least one index $i$.
18.3 Definition. Let $K+\Delta+\sum d_{i} D_{i}$ be a $\log$ canonical divisor on $X$. Assume that $D_{i}$ are $\mathbb{Q}$-Cartier Weil-divisors. We say that $K+\Delta+\sum d_{i} D_{i}$ is maximally log canonical near $Z \subset X$ if $\left(X, K+\Delta+\sum d_{i}^{\prime} D_{i}\right)$ is not log canonical in any neighborhood of $Z$ where $d_{i}^{\prime} \geq d_{i}$ with inequality holding for at least one index $i$.

Warning: It is important to note that this definition depends on the $\Delta$ and the $D_{i}$, not just on $\Delta+\sum d_{i} D_{i}$.

The following is clear:
18.4 Lemma. Let $K+\Delta+\sum d_{i} D_{i}$ be as above.
(18.4.1) Let $f: Y \rightarrow X$ be a log resolution. $K+\Delta+\sum d_{i} D_{i}$ is maximally $\log$ canonical in a neighborhood of $Z$ iff for every $D_{i}$ there is a divisor $E_{i} \subset Y$ with $\log$ discrepancy zero such that $f\left(E_{i}\right) \subset \operatorname{Supp} D_{i}$ and $Z \cap f\left(E_{i}\right) \neq \emptyset$.
(18.4.2) There is a (nonunique) sequence $d_{i}^{\prime} \geq d_{i}$ such that $(X, K+\Delta+$ $\left.\sum d_{i}^{\prime} D_{i}\right)$ is maximally $\log$ canonical in a neighborhood of $Z$.
(18.4.3) Assume that $K+\Delta+\sum d_{i} D_{i}$ is $\log$ terminal, $\left\llcorner d_{1} D_{1}\right\lrcorner=0$, and $D_{1}$ does not have any irreducible components in common with $\Delta$ or with $\sum_{k \neq 1} D_{k}$. Then we may assume that $d_{1}^{\prime}>d_{1}$.
18.5 Definition. $f:(X, K+S+B) \rightarrow Z$ is a limiting contraction if (18.5.1) $X$ is $\mathbb{Q}$-factorial and $f$ is small;
(18.5.2) $S$ is irreducible and $f$-negative;
(18.5.3) every irreducible component of $B$ is $f$-negative;
(18.5.4) $K+S+B$ is maximally $\log$ canonical in a neighborhood of $C$;
(18.5.5) $K+S$ is purely $\log$ terminal.
18.6 Definition. $f:(X, K+D) \rightarrow Z$ is a pre limiting contraction if (18.6.1) $X$ is $\mathbb{Q}$-factorial and $f$ is small;
(18.6.2) there exists $S \subset\llcorner D\lrcorner$ such that $S$ is $f$-negative;
(18.6.5) $K+D$ is $\log$ terminal.
18.7 Lemma. Let $f:(X, K+S+B) \rightarrow Z$ be a pre limiting contraction. Assume that $\rho(X / Z)=1$. Then there is a suitable $B^{\prime}$ such that
(18.7.1) $K+S+B^{\prime}$ is limiting.
(18.7.2) The flip of $K+S+B^{\prime}$ is isomorphic to the flip of $K+S+B$ (assuming they exist).
(18.7.3) $\operatorname{type}\left(S+B^{\prime}\right) \geq \operatorname{type}(S+B)$ and if $\{B\} \neq \emptyset$ then type $\left(S+B^{\prime}\right)>$ type $(S+B)$.

Proof. Since $\rho(X / Z)=1$, the flip of $f$ is independent of the choice of $S+B$ (2.32.1). We can throw away the components of $B$ which are $f$-semipositive. This gives $K+S+B_{1}$. By (18.4) we can increase the coefficients of $B_{1}$ until we get $B^{\prime}$ which is maximally $\log$ canonical near $C$.

The type increased or remained unchanged in both steps. It is unchanged only if $B=B_{1}$ and $\left\{B_{1}\right\}=\emptyset$.
18.8 Definition. $f:(X, K+S+B) \rightarrow Z$ is a special contraction if it is limiting, $K+S+B$ is lt and $B$ is reduced (possibly empty).

Our aim is to show that if flips of special contractions exist then all flips exist.
18.9 Theorem. (In dimension three only.) If the flip of any special contraction exists then the flip exists for any small contraction $f:(X, K+D) \rightarrow Z$ such that $K+D$ is klt.

Proof. This follows from (18.11) and (18.26).
We start with an explanation of the basic idea behind the proof.
18.10 Reduction Strategy. Assume for simplicity that $X$ is $\mathbb{Q}$-factorial. First we increase the coefficients of $D$ until $K+D$ becomes maximally log canonical. Then take a log resolution $h: Y \rightarrow X \rightarrow Z$ and apply the MMP to $K_{Y}+D_{Y}$. Since $K_{Y}+D_{Y}$ is log terminal, during the program we stay in the category of log terminal singularities. Therefore the program never leads back to the original $f: X \rightarrow Z$. Moreover, each time we need to flip, we can increase the coefficients further as in the first step. Thus we can use descending induction on the coefficients of $D$. If all technical details work out then ultimately we are reduced to flips of contractions $g:\left(X^{\prime}, D^{\prime}\right) \rightarrow Z^{\prime}$ where $D^{\prime}$ is reduced.

This simple picture has several technical and conceptual drawbacks.
(18.10.1) We need to know termination of flips in order to apply the procedure. Currently we know this in special cases only (cf. Chapter 7).
(18.10.2) The MMP stops when the birational transform of $K+D$ becomes nef. This is in general not the flip, only a log terminal model. The current base point freeness theorems are not strong enough to conclude the existence of the flip unless $\llcorner D\lrcorner=0$. (See, however, Chapter 8.)
(18.10.3) The main problem is that we are left with too many cases. Assume that we need to flip $g:\left(X^{\prime}, D^{\prime}\right) \rightarrow Z^{\prime}$ and $D^{\prime}$ is reduced. If $D^{\prime} \cdot C^{\prime}<0$ then $D^{\prime}$ contains the flipping curve $C^{\prime}$, thus $g$ is a special contraction. In this case the restriction $g \mid D^{\prime}: D^{\prime} \rightarrow g\left(D^{\prime}\right)$ captures many of the properties of $g: X^{\prime} \rightarrow Z^{\prime}$ and allows us to use results about (not necessarily small) contractions in dimension $\operatorname{dim} X-1$.

However if $D^{\prime} \cdot C^{\prime} \geq 0$ then we might as well throw away $D^{\prime}$, and we have no boundary at all. These cases include all terminal flips, which are already very difficult to handle.

Our aim is to have a reduction procedure where we always end up in the first case $D^{\prime} \cdot C^{\prime}<0$ of (18.10.3). This makes the reduction more complicated, but much more useful.

A large part of the proof applies in all dimensions. There are only two places where we use three dimensional results. The first result we need is that limiting flips terminate. The second result concerns log canonical singularities and is discussed in detail later (18.15-26).
18.11 Proposition. Assume that flips of pre limiting contractions exist, and that any sequence of them terminates. Then
(18.11.1) For every small contraction $f:(X, D) \rightarrow Z$ there exists a $\mathbb{Q}$ factorial log terminal model.
(18.11.2) If $K+D$ is klt then the flip of $f$ exists.

The following improved version of (18.10) is based on [Shokurov91,6.4-5]. Our choice of $H^{\prime}$ is slightly different. The advantage is that we do not need to use semi stable flips later on.

### 18.12 Log Flipping Procedure.

Start with $(X, K+D)$ arbitrary and let $f: X \rightarrow Z$ be a small contraction. Let $T \subset Z$ be the exceptional set of $f^{-1}$.
(18.12.1) Let $H^{\prime}$ be a Cartier divisor on $Z$ such that
(18.12.1.1) $H=f^{*} H^{\prime}$ contains the exceptional locus of $f$.
(18.12.1.2) $H^{\prime}$ contains the singular locus of $Z$ and the singular locus of the support of $f(D)$.
(18.12.1.3) Fix a resolution $\pi: Z^{\prime} \rightarrow Z$. Let $F_{j} \subset Z^{\prime}$ be divisors which generate $N^{1}\left(Z^{\prime} / Z\right)$. We assume that $H^{\prime}$ contains $\pi\left(F_{j}\right)$ for every $j$. (This usually implies that $H^{\prime}$ is reducible.)

The main consequence of the last assumption is the following:
(18.12.1.4) Let $h: Y \rightarrow Z$ be any proper birational morphism such that $Y$ is $\mathbb{Q}$-factorial. Then the irreducible components of the birational transform of $H^{\prime}$ and the exceptional divisors generate $N^{1}(Y / Z)$.
(18.12.2) We claim that there is a $\log$ resolution $h: Y \rightarrow X \rightarrow Z$ for $K+D+H$ which is an isomorphism over $Z \backslash H^{\prime}$. Indeed, first we can resolve the singularities of $Z$; for this we need to blow up only inside the singular set. Then we resolve the singularities of the inverse image of $H^{\prime} \cup D$; for this again we need to blow up only inside the singular set which is contained in the preimage of $H^{\prime}$.

Then $K_{Y}+(D+H)_{Y}$ is $\mathbb{Q}$-factorial and log terminal. Observe that $h^{*}\left(H^{\prime}\right)$ contains $h^{-1}(T), h^{*}\left(H^{\prime}\right)$ is LSEPD with respect to $h$ and $h^{*}\left(H^{\prime}\right)$ contains all exceptional divisors.
(18.12.3) Apply the $Y / Z$-Minimal Model Program to $K_{Y}+(D+H)_{Y}$ over a neighborhood of $T$. We successively construct the objects $\left(h_{i}: Y_{i} \rightarrow Z, K_{Y_{i}}+\right.$ $\left.(D+H)_{Y_{i}}\right) .\left\llcorner(D+H)_{Y_{i}}\right\lrcorner$ contains the support of $h_{i}^{*} H$, and every flipping curve is contained in $\operatorname{supp} h_{i}^{*} H$ which is LSEPD. Termination of flips needs to be established. If we can perform the flips then we end up with a $\mathbb{Q}$-factorial $\log$ terminal model $\bar{h}:\left(\bar{Y}, K_{\bar{Y}}+(D+H)_{\bar{Y}}\right) \rightarrow Z$.
(18.12.4) Our next goal is to remove the birational transform $\bar{H}^{\prime}$ of $H^{\prime}$ from $(D+H)_{\bar{Y}}$.

By definition $K_{\bar{Y}}+(D+H)_{\bar{Y}}$ is $\bar{h}$-nef. Consider the largest $\epsilon$ in the range $0 \leq \epsilon \leq 1$ such that $K_{\bar{Y}}+(D+H)_{\bar{Y}}-\epsilon \bar{H}^{\prime}$ is $\bar{h}$-nef. If $\epsilon=1$ then

$$
K_{\bar{Y}}+D_{\bar{Y}}=K_{\bar{Y}}+(D+H)_{\bar{Y}}-\bar{H}^{\prime}
$$

is $\bar{h}$-nef, hence $\bar{h}: \bar{Y} \rightarrow Z$ is a log terminal model.
Otherwise we try to increase $\epsilon$ as follows. Take $0<\eta \ll \epsilon$. Then

$$
K_{\bar{Y}}+(D+H)_{\bar{Y}}-(\epsilon+\eta) \bar{H}^{\prime}
$$

is not nef. We can apply the relative Minimal Model Program. We successively construct the objects

$$
\left(\bar{h}_{i}: \bar{Y}_{i} \rightarrow Z, K_{\bar{Y}_{i}}+(D+H)_{\bar{Y}_{i}}-(\epsilon+\eta) \bar{H}_{i}^{\prime}\right) .
$$

By construction $(D+H)_{\bar{Y}}-(\epsilon+\eta) \bar{H}^{\prime}$ is LSEPD, thus by (2.35) there are only finitely many $\left(K_{\bar{Y}}+(D+H)_{\bar{Y}}-(\epsilon+\eta) \bar{H}^{\prime}\right)$-extremal rays. Therefore we may assume that if $C_{i}$ is a flipping curve, then

$$
\begin{equation*}
\left(K_{\bar{Y}_{i}}+(D+H)_{\bar{Y}_{i}}-(\epsilon+\eta) \bar{H}_{i}^{\prime}\right) \cdot C_{i}=-\eta \bar{H}_{i}^{\prime} \cdot C_{i}<0, \tag{18.12.4.1}
\end{equation*}
$$

hence $\bar{H}_{i}^{\prime} \cdot C_{i}>0$. Also $0=\bar{h}_{i}^{*} H^{\prime} \cdot C_{i}=\bar{H}_{i}^{\prime} \cdot C_{i}+\sum \alpha_{k} E_{k} \cdot C_{i}$, where all the $\alpha_{k}$ are nonnegative integers and the $E_{k}$ are $\bar{h}_{i}$-exceptional. Then $E_{k} \cdot C_{i}<0$ for some index $k$ and $C_{i} \subset E_{k} \subset\left\llcorner(D+H)_{\bar{Y}_{i}}\right\lrcorner$.

If these flips exist and terminate then we obtain

$$
\left(\bar{h}_{k}: \bar{Y}_{k} \rightarrow Z, K_{\bar{Y}_{k}}+(D+H)_{\bar{Y}_{k}}-(\epsilon+\eta) \bar{H}_{k}^{\prime}\right)
$$

such that $K_{\bar{Y}_{k}}+(D+H)_{\bar{Y}_{k}}-(\epsilon+\eta) \bar{H}_{k}^{\prime}$ is $\bar{h}_{k}$-nef. Thus we can increase the value of $\epsilon$ to $\epsilon^{\prime} \geq \epsilon+\eta$. Next apply the

$$
K_{\bar{Y}_{k}}+(D+H)_{\bar{Y}_{k}}-\left(\epsilon^{\prime}+\eta^{\prime}\right) \bar{H}_{k}^{\prime}
$$

Minimal Model Program as before, and so on.
We claim that after finitely many steps we reach $\epsilon=1$. The only question is the termination of flips. This is however slightly more delicate than usual since we have to account for the possibility that we have an infinite sequence of $\left(K+(D+H)_{Y}-\epsilon \bar{H}\right)$-flips during which the choice of $\epsilon$ changes. However from (18.12.4.1) it follows that for every such flip

$$
\left(K_{\bar{Y}_{i}}+(D+H)_{\bar{Y}_{i}}-\bar{H}_{i}^{\prime}\right) \cdot C_{i}<0,
$$

thus our sequence of $\left(K+(D+H)_{Y}-\epsilon \bar{H}\right)$-flips is also a sequence of $(K+$ $\left.(D+H)_{Y}-\bar{H}\right)$-flips. Hence we face only the usual termination problem which is settled in chapter 7.
(18.12.5) If all the above flips exist and terminate then at the end we obtain

$$
\tilde{h}:\left(\tilde{Y}, K_{\tilde{Y}}+D_{\tilde{Y}}\right) \rightarrow Z
$$

such that $\tilde{Y}$ is $\mathbb{Q}$-factorial, $K_{\tilde{Y}}+D_{\tilde{Y}}$ is log terminal and $\tilde{h}$-nef.
18.13 Proof of (18.11). Let $f:(X, K+D) \rightarrow Z$ be a pre limiting contraction. Apply the log flipping procedure (18.12).

We claim that during the procedure only pre limiting flips are used. If $C_{i}$ is a flipping curve in (18.12.3) then $C_{i} \subset h_{i}^{*} H^{\prime}$ and $C_{i} \cdot h_{i}^{*} H^{\prime}=0$. By (18.12.1.4) there is an irreducible component $F_{i} \subset h_{i}^{*} H^{\prime}$ such that $C_{i} \cdot F_{i} \neq 0$. Thus a suitable irreducible component of $h_{i}^{*} H^{\prime}$ intersects $C_{i}$ negatively. We throw away those components of $(D+H)_{Y_{i}}$ which intersect $C_{i}$ nonnegatively. Write the remaining components as $S+B$ where the components of $S$ have coefficient one and the components of $B$ have coefficient $<1$.

In step (18.12.4) we proved that $C_{i} \cdot E_{k}<0$, therefore we obtain a pre limiting contraction.

By assumption every step of the log flipping procedure exists and we assume termination. At the end we obtain a $\mathbb{Q}$-factorial log terminal model $\tilde{h}: \tilde{Y} \rightarrow Z$.

If $K+D$ is klt, then $K_{\tilde{Y}}+\tilde{D}_{Y}$ is also klt, hence the flip of $f$ exists by (2.29).

The following refinement of (18.11) is crucial in the next step.
18.14 Proposition. Let $f:(X, K+S+B) \rightarrow Z$ be a limiting contraction. Assume that $\rho(X / Z)=1$. Assume moreover that
(18.14.1) The flip of every limiting contraction of greater type exists.
(18.14.2) The flip of every special contraction exists.
(18.14.3) Pre limiting flips terminate.

Then the flip of $f$ also exists.
Proof. As before let $T \subset Z$ be the exceptional set of $f^{-1}$.
As a first step we construct a $\log$ terminal model of $(X, K+S+B)$. To do this we take a log resolution $p: X^{\prime} \rightarrow X$ and apply the ( $K_{X^{\prime}}+(S+B)_{X^{\prime}}$ )MMP relative to a neighborhood of $S \subset X$. In the course of the program we have to make certain flips with flipping curve $C$. All flipping curves are contained in

$$
\operatorname{Supp}\left(p^{*} S\right) \subset\left\llcorner(S+B)_{X^{\prime}}\right\lrcorner .
$$

By the proof of (2.16.2) the exceptional divisor of $p$ supports a divisor $E$ such that $-E$ is $p$-ample. Thus $C \cdot E<0$ and the contraction of $C$ is pre limiting.

Let $B=\sum_{1}^{k} b_{i} B_{i}$. Then type $(S+B)=\left(b_{1}, \ldots, b_{k}\right)$. On $X^{\prime}$ the only divisors in $(S+B)_{X^{\prime}}$ with coefficient $<1$ are the birational transforms $B_{i}^{\prime}$. In order to make a contraction limiting, first we throw away those $B_{j}^{\prime}$ which have nonnegative intersection with $C$. Then we can increase the coefficients as in (18.7). Thus the corresponding limiting contraction of $C$ is either special or it has type strictly greater than type $(S+B)$.

Thus the existence of the flip of $C$ follows from the existence of limiting flips of greater type and of special flips.

At the end we obtain $g: Y \rightarrow X$ which is a $\mathbb{Q}$-factorial $\log$ terminal model. In particular,

$$
K_{Y}+(S+B)_{Y} \equiv g^{*}\left(K_{X}+S+B\right) .
$$

Next let $H^{\prime}$ be a sufficiently general and sufficiently $f$-ample divisor on $X$. Let $H=g^{*} H^{\prime}$. For some $0<\epsilon<1, K+S+B+\epsilon H^{\prime}$ is numerically $f$-trivial and $K_{Y}+(S+B)_{Y}+\epsilon H$ is log terminal and numerically $f \circ g$-trivial. For some $0<\eta \ll \epsilon$ apply the MMP for

$$
K_{Y}+(S+B)_{Y}+(\epsilon-\eta) H
$$

to $Y / Z$. During the course of the program the birational transform of $K_{Y}+$ $(S+B)_{Y}+\epsilon H$ remains numerically trival over $Z$. Thus if $C_{i}$ is a flipping curve in the $i^{\text {th }}$-step of the program then $C_{i} \cdot H_{i}>0$. Therefore the contraction corresponding to $C_{i}$ is a $\left(K_{Y_{i}}+(S+B)_{Y_{i}}\right)$-extremal contraction. We claim that it is pre limiting and of type at least the type of $S+B$. The statement about the type can be proved as before.

Let $S_{1} \subset S$ be such that $C \cdot S_{1}<0$. Since $H^{\prime} \cdot C>0$, there is an $\alpha>0$ such that $S_{1}+\alpha H^{\prime}$ is numerically $f$-trivial. Thus $g^{*}\left(S_{1}+\alpha H\right)$ is numerically $f \circ g$-trivial, and it contains $(f \circ g)^{-1}(T)$. The same properties continue to hold for its birational transform on $Y_{i}$ for every $i$. By assumption $C_{i} \cdot H>0$, hence $\left(g^{*} S_{1}\right)_{i} \cdot C_{i}<0$. Therefore there is an irreducible component of

$$
\operatorname{Supp}\left(g^{*} S_{1}\right)_{i} \subset\left\llcorner(S+B)_{Y_{i}}\right\lrcorner
$$

which intersects $C_{i}$ negatively.
At the end we obtain $\bar{g}: \bar{Y} \rightarrow Z$ such that

$$
K_{\bar{Y}}+(S+B)_{\bar{Y}}+(\epsilon-\eta) \bar{H}
$$

is $\bar{g}$-nef. $S+B+(\epsilon-\eta) H^{\prime}$ is LSEPD with respect to $f$, and thus the flip of $f$ exists by (2.32.2) and (2.29.1).
(18.14) is very useful if there is no infinite increasing sequence of limiting contractions. At first sight there is no reason why such a sequence should not exist. [Shokurov88,91] discovered that there are many situations where a similar ordering of the coefficients makes sense, and, at least conjecturally, there are no infinite increasing sequences. Below we define some of these sets of sequences. Later we prove some relationships between them and finally we show the nonexistence of infinite increasing sequences in low dimensional cases.

### 18.15 Definition.

(18.15.1) $\mathcal{S}_{n}$ (fano) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is an a smooth and proper Fano variety $X$ of dimension at most $n$ and a divisor $\sum b_{i} B_{i}$ such that $\rho(X)=1, K_{X}+\sum b_{i} B_{i}$ is $\log$ canonical, log terminal outside $\sum B_{i}$ and numerically trivial.
(18.15. $\overline{1}) \mathcal{S}_{n}$ (global) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is a proper variety $X$ of dimension at most $n$ and a divisor $\sum b_{i} B_{i}$ such that $K_{X}+\sum b_{i} B_{i}$ is $\log$ canonical, $\log$ terminal outside $\sum B_{i}$ and numerically trivial.
(18.15.2) $\mathcal{S}_{n}$ (local) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is a pointed a $\mathbb{Q}$-factorial variety $x \in X$ of dimension at most $n$ and a divisor $\sum b_{i} B_{i}$ such that $x \in \cap B_{i}$ and $K_{X}+\sum b_{i} B_{i}$ is maximally log canonical at $x$.
$(18.15 . \overline{2}) \overline{\mathcal{S}}_{n}$ (local) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is a $\mathbb{Q}$-factorial variety $X$ of dimension at most $n$, a closed subset $Z \subset X$ and a divisor $\sum b_{i} B_{i}$ such that every $B_{i}$ intersects $Z$ and $K_{X}+\sum b_{i} B_{i}$ is maximally $\log$ canonical near $Z$.
(18.15.3) $\mathcal{S}_{n}^{0}$ (local) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is a pointed a $\mathbb{Q}$-factorial variety $x \in X$ of dimension at most $n$ and a divisor $B_{0}+\sum b_{i} B_{i}\left(B_{0} \neq 0\right.$ is reduced but possibly reducible) such that $x \in \cap B_{i}$, $K_{X}+B_{0}$ is purely $\log$ terminal and $K_{X}+B_{0}+\sum b_{i} B_{i}$ is maximally $\log$ canonical at $x$. (Purely $\log$ terminal implies that $B_{0}$ is locally irreducible.)
(18.15. $\overline{3}) \overline{\mathcal{S}}_{n}^{0}$ (local) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is an a $\mathbb{Q}$-factorial variety $X$ of dimension at most $n$, a subset $Z \subset X$ and a divisor $B_{0}+\sum b_{i} B_{i}\left(B_{0} \neq 0\right.$ is reduced but possibly reducible) such that every $B_{i}$ intersects $Z, Z \subset B_{0}, K_{X}+B_{0}$ is purely $\log$ terminal and $K_{X}+B_{0}+\sum b_{i} B_{i}$ is maximally $\log$ canonical near $Z$.
18.16 Conjecture. The ascending chain condition holds for any of the six sets in (18.15). (With respect to the ordering given in (18.2.2)).

For technical reasons we also need the following rather complicated definition. We try to formalize the properties of the different (16.6-7).
18.17 Definition. $\mathcal{S}_{n}$ (local diff) is the set of sequences $\left(b_{1}, \ldots, b_{m}\right)$ such that there is a pointed a variety $x \in X$ of dimension at most $n$ and a divisor $K+\Delta+\sum b_{i} B_{i}$ such that
(18.17.1) $x \in \cap \operatorname{Supp} B_{i}$,
(18.17.2) $K+\Delta$ is purely $\log$ terminal and $K+\Delta+\sum b_{i} B_{i}$ is maximally $\log$ canonical at $x$.
(18.17.3) $\Delta=\sum\left(1-1 / m_{j}\right) \Delta_{j}$ where $\Delta_{j}$ are irreducible, reduced and the $m_{j}$ are natural numbers (we allow $m_{j}=1$ );
(18.17.4) $B_{i}$ is $\mathbb{Q}$-Cartier for every $i$ and $B_{i}=\sum_{j}\left(s_{i j} / m_{j}\right) \Delta_{j}$ for some integers $s_{i j} \geq 0$ such that $\sum_{j} s_{i j}>0$.

It is clear that $\mathcal{S}_{n}($ local $) \subset \mathcal{S}_{n}$ (local diff).
18.18 Definition. Let $\mathcal{L}$ be a set of sequences. We define two other sets of sequences $\overline{\mathcal{L}}$ and $D^{-1}(\mathcal{L})$ as follows:
(18.18.1) $\left(b_{1}, \ldots, b_{n}\right) \in \overline{\mathcal{L}}$ if and only if for every $1 \leq j \leq n$ there is a subset $\left(i_{1}, \ldots, i_{k(j)}\right)$ of $(1, \ldots, n)$ containing $j$ such that $\left(b_{i_{1}}, \ldots, b_{i_{k(j)}}\right) \in \mathcal{L}$.
(18.18.2) Let $D^{-1}(\mathcal{L})$ be the set of sequences $\left(b_{1}, \ldots, b_{n}\right)$ such that $0<$ $b_{i} \leq 1$ for every $i$ and the following holds:

There is a natural number $k$ and positive integers $r_{h}$, integers $0 \leq s_{h i} \leq r_{h}$, and $t_{h} \in\{0,1\}$ for every $1 \leq h \leq k$ and $1 \leq i \leq n$ such that

$$
\begin{aligned}
& p_{h}=\frac{r_{h}-1}{r_{h}}+\sum_{i=0}^{n} \frac{s_{h i}}{r_{h}} b_{i}+\frac{t_{h}}{r_{h}} \leq 1 \quad \text { for every } h \\
& \left(p_{1}, \ldots, p_{k}\right) \in \mathcal{L} ; \text { and } \\
& \max _{h}\left\{s_{h i}\right\}>0 \text { for every } 1 \leq i \leq n
\end{aligned}
$$

(18.18.3) The following two properties are easy to check:

$$
\overline{\overline{\mathcal{L}}}=\overline{\mathcal{L}} \quad \text { and } \quad \overline{D^{-1}(\mathcal{L})}=D^{-1}(\overline{\mathcal{L}}) .
$$

(18.18.4) From (7.4.3) we see that $D^{-1}\left(D^{-1}(\mathcal{L})\right)=D^{-1}(\mathcal{L})$.

The barred versions of (18.15) are related to the others in a very simple way:

### 18.19 Proposition.

(18.19.1) $\overline{\mathcal{S}}_{n}($ local $) \subset \overline{\mathcal{S}_{n}(\text { local })} ;$
(18.19.2) $\overline{\mathcal{S}}_{n}^{0}($ local $) \subset \overline{\mathcal{S}_{n}^{0}(\text { local }) ; ~}$
(18.19.3) $\mathcal{L}$ satisfies the ascending chain condition iff $\overline{\mathcal{L}}$ does.

Proof. Let $f: Y \rightarrow X$ be a $\log$ resolution. For every $B_{j}$ there is a divisor $E_{j} \subset Y$ as in (18.4.1). Let $x_{j} \in X$ be the image of the generic point of $E_{j}$. Let $i=i_{1}, \ldots, i_{k}$ be those indices such that $x_{j} \in B_{i}$. Then

$$
K_{X}+\sum_{l=1}^{k} B_{i_{l}}
$$

is maximally $\log$ canonical at $x_{j}$. This proves (18.19.1), and (18.19.2) is proved the same way.

Clearly $\mathcal{L} \subset \overline{\mathcal{L}}$. Assume that $\mathcal{L}$ satisfies the ascending chain condition. Let

$$
\mathbf{b}_{1} \leq \mathbf{b}_{2} \leq \ldots
$$

be an infinite ascending chain where

$$
\mathbf{b}_{i}=\left(b_{1}^{i}, \ldots, b_{n(i)}^{i}\right) \in \overline{\mathcal{L}}
$$

We may assume that $n=n(i)$ is constant. By definition, for every $i$ we have a covering of $(1, \ldots, n)$ by $n$ subsets. By passing to a subsequence we may assume that the covering does not depend on $i$. Thus for every $i$ we get $n$ sequences $\mathbf{b}_{i}^{j} \in \mathcal{L}$ such that,

$$
\mathbf{b}_{1}^{j} \leq \mathbf{b}_{2}^{j} \leq \ldots \quad \forall j,
$$

and for every $i$ at least one of the inequalities $\mathbf{b}_{i}^{j} \leq \mathbf{b}_{i+1}^{j}$ is strict. This is impossible since $\mathcal{L}$ satisfies the ascending chain condition.

The following was pointed out by Alexeev:
18.19.4 Proposition. Assum the log MMP for dimension $n$. Then

$$
\mathcal{S}_{n}(\text { global }) \subset \overline{\mathcal{S}_{n}(\text { fano })}
$$

Proof. Let $\left(X, \sum b_{i} B_{i}\right) \in \mathcal{S}_{n}$ (global). As in (8.8.1) let $f: X^{\prime} \rightarrow X$ be a small morphism such that $X^{\prime}$ is $\mathbb{Q}$-factorial. Then $\left(X^{\prime}, \sum b_{i} B_{i}^{\prime}\right) \in \mathcal{S}_{n}$ (global). We prove by induction on $\operatorname{dim} X^{\prime}$ and $\operatorname{rank} \operatorname{Pic}\left(X^{\prime}\right)$ that $\left(b_{1}, \ldots, b_{m}\right) \in \overline{\mathcal{S}_{n}(\text { fano })}$. Fix $k$ and consider the ( $\left.K+\sum b_{i} B_{i}^{\prime}-\epsilon B_{k}^{\prime}\right)$-MMP. After possibly some flips $X^{\prime} \rightarrow X^{\prime \prime}$, we perform a divisorial or a Fano contraction $g: X^{\prime \prime} \rightarrow Z . B_{k}^{\prime \prime}$ is positive on the extremal ray of $g$, thus $B_{k}^{\prime \prime}$ is not contracted by $g$ in the divisorial case, and intersects the general fiber in the Fano case.

If $g$ is divisorial, then $\operatorname{rank} \operatorname{Pic}\left(X^{\prime}\right)=\operatorname{rank} \operatorname{Pic}\left(X^{\prime \prime}\right)>\operatorname{rank} \operatorname{Pic}(Z)$ and we are done by induction on rank Pic. If $g$ is Fano then we can restrict everything to the general fiber of $g$ and conclude by induction on the dimension.
18.20 Definition. Let $\mathcal{L}$ be a set of sequences. We say that $\mathcal{L}$ has bounded sums if there is an $M$ such that $\sum b_{i}<M$ for every $\left(b_{1}, \ldots, b_{k}\right) \in \mathcal{L}$.

The various cases in (18.15) and (18.17) are related by the following result.

### 18.21 Theorem. (Inductive Principle)

(18.21.1) $\mathcal{S}_{n}^{0}($ local $) \subset \mathcal{S}_{n-1}$ (local diff).
(18.21.2) Assume that for every $n$-dimensional log canonical variety ( $X, K+$ $D)$ there is a $\mathbb{Q}$-factorial log terminal model $f: Y \rightarrow X$. Then

$$
\mathcal{S}_{n}(\text { local diff }) \subset \overline{D^{-1}\left(\mathcal{S}_{n-1}(\text { global })\right)} .
$$

(18.21.3) If $\mathcal{L}$ has bounded sums then so does $D^{-1}(\mathcal{L})$.
(18.21.4) If $\mathcal{L}$ has the ascending chain condition and has bounded sums then so does $D^{-1}(\mathcal{L})$.
Proof. We start with (18.21.1). Let $\left(b_{1}, \cdots, b_{k}\right)$ be a sequence in $\mathcal{S}_{n}^{0}$ (local). By assumption there exists an $n$-dimensional variety $X$ and a divisor $S+\sum b_{i} D_{i}$, with $S$ reduced and irreducible, such that $K_{X}+S+\sum b_{i} D_{i}$ is maximally log canonical at a point $x \in \cap D_{i} \subset X$. Set

$$
\Delta=\operatorname{Diff}_{S}(0) \quad \text { and } \quad B_{i}=i^{w} \mathcal{O}_{X}\left(D_{i}\right)
$$

where $i: S \rightarrow X$ is the natural injection and $i^{w}$ is defined in (16.3.6). By (16.6) $K+\Delta+\sum b_{i} B_{i}$ satisfies the conditions (18.7.3-4) and by (17.8) it also satisfies (18.17.2). Thus $\left(b_{1}, \cdots, b_{k}\right) \in \mathcal{S}_{n-1}$ (local diff). This proves (18.21.1).

The proof of (18.21.2) is similar. Pick $\left(b_{1}, \cdots, b_{k}\right) \in \mathcal{S}_{n}$ (local diff). By hypothesis there exists an $n$-dimensional pair ( $X, K+\Delta+\sum b_{i} B_{i}$ ) which is maximally $\log$ canonical at a point $x \in X$. Let $\delta_{j}$ be the coefficient of $\Delta_{j}$ in $\Delta+\sum b_{i} B_{i}$. Let $f: Y \rightarrow X$ be a $\mathbb{Q}$-factorial log terminal model. Let $\Delta_{j}^{\prime} \subset Y$ be the birational transform of $\Delta_{j}$ and let $E_{k} \subset Y$ be the exceptional divisors. Pick $E_{0}$ such that $x \in f\left(E_{0}\right)$. By (17.5) $E_{0}$ is normal. Then

$$
0 \equiv f^{*}\left(K+\Delta+\sum b_{i} B_{i}\right) \mid E_{0} \equiv K_{E_{0}}+\operatorname{Diff}\left(\sum_{k \neq 0} E_{k}+\sum \delta_{j} \Delta_{j}^{\prime}\right),
$$

where $\equiv$ means numerical equivalence relative to $f$. By (16.6) and (7.4.3)

$$
\operatorname{Diff}_{E_{0}}\left(\sum_{k \neq 0} E_{k}+\sum \delta_{j} \Delta_{j}^{\prime}\right)=\sum p_{h} D_{h},
$$

where $D_{h} \subset E_{0}$ are divisors and the coefficients $p_{h}$ are computed by the formula in (18.18.2) for suitable $r_{h}, s_{h i}$ and $t_{h}$. (The presence of the $E_{k}$ are the reason of using $t_{h}$ in (18.18.2).) If $E_{0}$ is not proper then replace it with the general fiber of $E_{0} \rightarrow f\left(E_{0}\right)$. The last assumption of (18.18.2) is not necessarily satisfied since some of the $f_{*}^{-1}\left(B_{i}\right)$ may not intersect $E_{0}$. By (18.4) for every $B_{i}$ there is an exceptional divisor $E_{k}$ such that $f_{*}^{-1}\left(B_{i}\right)$ intersects the general fiber of $E_{k} \rightarrow f\left(E_{k}\right)$.

Let $E_{0}$ run through all exceptional divisors such that $x \in f\left(E_{0}\right)$. This proves (18.21.2).

From the formula for $p_{h}$ it is easy to see that

$$
p_{h} \geq \sum_{\left\{i: s_{h i} \neq 0\right\}} b_{i} .
$$

Thus $\sum p_{h} \geq \sum b_{i}$, and hence $D^{-1}(\mathcal{L})$ has bounded sums if $\mathcal{L}$ has. This proves (18.21.3).

Finally, consider (18.21.4). Assume that we have an infinite increasing sequence $\mathbf{b}^{1}<\mathbf{b}^{2}<\ldots$. By passing to a subsequence we may assume that they all have the same length $\mathbf{b}^{j}=\left(b_{1}^{j}, \ldots, b_{n}^{j}\right)$.

We use an upper index $j$ to refer to a formula (18.18.2) associated to $\mathbf{b}^{j}$. The symbols $k^{j}, p_{h}^{j}, r_{h}^{j}, s_{h i}^{j}, t_{h}^{j}$ are as in (18.18.2). The numbers $b_{i}^{j}$ are bounded from below by $\mu=\min \left\{b_{i}^{1}\right\}>0$, and thus $p_{h}^{j} \geq \mu$ hence $\sum p_{h}^{j} \geq k^{j} \mu$ which shows that $k^{j}$ is bounded. Thus by passing to a subsequence we may assume that $k^{j}=k$ is independent of $j$.
18.21.5 Claim. For each fixed index $h,\left\{p_{h}^{j}\right\}$ has an infinite nondecreasing subsequence.
Proof. We drop the index $h$ from the notation. By assumption

$$
p^{j}=\frac{r^{j}-1}{r^{j}}+\sum_{i} \frac{s_{i}^{j}}{r^{j}} b_{i}^{j}
$$

Since $p^{j} \leq 1$ we obtain

$$
\sum_{i} s_{i}^{j} b_{i}^{j} \leq 1
$$

The numbers $b_{i}^{j}$ are bounded from below by $\mu>0$, hence $s_{i}^{j}$ are bounded from above by a constant. By passing to a subsequence we may thus assume that $s_{i}^{j}=s_{i}$ are independent of $j$. Set $u^{j}=\sum s_{i} b_{i}^{j}$, then $u^{j}$ is a nondecreasing sequence of real numbers, and $u^{j} \leq 1$. By passing to a subsequence we may also assume that $r^{j}$ is nondecreasing. Thus

$$
p^{j}=\frac{r^{j}-1}{r^{j}}+\frac{u^{j}}{r^{j}}=1-\frac{1-u^{j}}{r^{j}}
$$

is also nondecreasing.
Observe furthermore that $p^{j}$ is strictly increasing if the sequence $r^{j}$ is strictly increasing.

We continue with the proof of (18.21). By passing to a subsequence we may assume that $s_{h i}^{j}=s_{h i}$ are all independent of $j$ and $r_{h}^{j}$ is either constant or increasing for every $h$. We obtain that $\mathbf{p}^{1} \leq \mathbf{p}^{2} \leq \ldots$ and the sequence is strictly increasing if one of the sequences $r_{h}^{j}$ is strictly increasing.

We are left with the case when in addition $r_{h}^{j}=r_{h}$ is also independent of $j$. Then

$$
\begin{aligned}
\sum_{h} p_{h}^{j} & =\sum_{h} \frac{r_{h}-1}{r_{h}}+\sum_{i}\left(\sum_{h} \frac{d_{h i}}{r_{h}}\right) b_{i}^{j} \\
& =C_{0}+\sum C_{i} b_{i}^{j}
\end{aligned}
$$

where the $C_{i}$ are positive and independent of $j$. Since the sequence $\mathbf{b}^{j}$ is strictly increasing, the same holds for $\sum_{h} p_{h}^{j}$, hence for the sequence $\mathbf{p}^{j}$.
18.22 Theorem. Let $\left(X, \sum b_{i} B_{i}\right)$ be $\log$ canonical at a point $x \in \cap B_{i}$. Assume that $K_{X}$ and $B_{i}$ are all $\mathbb{Q}$-Cartier at $x$. Then $\sum b_{i} \leq \operatorname{dim} X$.

In particular, $\mathcal{S}_{n}$ (local) has bounded sums.
Proof. The problem is clearly local. The claim is clear if $n=1$.
By taking repeated cyclic covers we may assume that the $B_{i}=\left(f_{i}=0\right)$ are Cartier. Assume that $\sum b_{i} \geq n=\operatorname{dim} X$. Let $\bar{B}=\left(\sum c_{i} f_{i}=0\right)$ for general $c_{i} \in \mathbb{C}$. Let $g: Y \rightarrow X$ be any $\log$ resolution of $\left(X, \bar{B}+\sum B_{i}\right)$ with exceptional divisors $E_{j}$. By specializing $g^{*} \bar{B}$ to $g^{*} B_{i}$ we obtain

$$
g_{*}^{-1}(\bar{B}) \sim g_{*}^{-1}\left(B_{i}\right)+\sum e_{i j} E_{j}
$$

where $e_{i j} \geq 0$. Thus if $0 \leq b_{i}^{\prime} \leq b_{i}$ and $\sum b_{i}^{\prime}=1$ then

$$
a\left(E_{j}, \bar{B}+\sum\left(b_{i}-b_{i}^{\prime}\right) B_{i}\right)=a\left(E_{j}, \sum b_{i} B_{i}\right)+\sum b_{i}^{\prime} e_{i j}
$$

Repeating this procedure we eventually obtain an lc pair

$$
\left(X, \bar{B}_{1}+\cdots+\bar{B}_{n}+\Delta\right)
$$

where the $\bar{B}_{i}$ are general Cartier divisors (with coefficient one) and $\Delta=$ $\sum d_{i} B_{i}$ is some other divisor such that $\sum d_{i}=\sum b_{i}-n$.

By (17.2)

$$
\left(\bar{B}_{n},\left(\sum_{i=1}^{n-1} \bar{B}_{i}\right) \mid \bar{B}_{n}+\operatorname{Diff}(\Delta)\right)
$$

is also lc. Thus $\Delta=0$ by induction on $\operatorname{dim} X$.
18.23 Complement. The above argument in fact shows that if the $B_{i}$ are Cartier and $\sum b_{i}>\operatorname{dim} X-1$ then $X$ is smooth at $x$. Indeed, in this case we can replace

$$
\sum_{i=1}^{n} b_{i} B_{i} \quad \text { by } \quad \sum_{i=1}^{n-1} \bar{B}_{i}+\Delta
$$

By induction on the dimension $\bar{B}_{n-1}$ is smooth hence so is $X$.
Similarly, if the $B_{i}$ and $K_{X}$ are Cartier and $\sum b_{i}>\operatorname{dim} X-2$ then $x \in X$ is a cDV point.

Combining (18.21) and (18.22) we obtain:
18.24 Corollary. Let $X$ be an $n$-dimensional Fano variety with $\rho(X)=1$ and let $\sum b_{i} B_{i}$ be a $\mathbb{Q}$-divisor such that $K_{X}+\sum b_{i} B_{i}$ is lc and numerically trivial. Then $\sum b_{i} \leq \operatorname{dim} X+1$.

In particular, $\mathcal{S}_{n}$ (fano) has bounded sums.
Proof. Choose an embedding $X \subset \mathbb{P}^{N}$ and let $y \in Y$ be the cone over $X$ with vertex $y$. Let $B_{i}^{\prime} \subset Y$ be the cone over $B_{i} .\left(B_{i}^{\prime}\right.$ is $\mathbb{Q}$-Cartier since $\rho(X)=1$.) It is easy to see that $\left(Y, \sum b_{i} B_{i}^{\prime}\right)$ is lc. Thus (18.22) implies (18.24).
18.24.1 Remark. $\mathcal{S}_{2}$ (global) does not have bounded sums. Indeed, assume that $D \in\left|-K_{X}\right|$ is reduced with only nodes. Blowing up a node gives $p: X^{\prime} \rightarrow X$ and $p^{-1}(D) \in\left|-K_{X^{\prime}}\right|$ has one more components than $D$. Thus there are surface examples with arbitrary many reduced components in a member of $\left|-K_{X}\right|$.
18.25 Theorem. Assume the $\log M M P$ in dimension $n-1$. Assume that the ascending chain condition holds for $\mathcal{S}_{n-2}($ fano $)$. Then the ascending chain condition also holds for $\mathcal{S}_{n-1}$ (local) and $\mathcal{S}_{n}^{0}$ (local).
Proof. By (18.18.3), (18.19.4) and (18.21.2)

$$
\mathcal{S}_{n-1}(\text { local diff }) \subset \overline{D^{-1}\left(\mathcal{S}_{n-2}(\text { global })\right)}=\overline{D^{-1}\left(\mathcal{S}_{n-2}(\text { fano })\right)}
$$

Therefore by (18.21.4) and (18.24) the ascending chain condition holds for $\mathcal{S}_{n-1}$ (local diff). The rest follows from (18.21.1) and (18.17).
18.25.1 Corollary. The ascending chain condition holds for $\mathcal{S}_{1}$ (global), $\mathcal{S}_{2}$ (local) and $\mathcal{S}_{3}^{0}$ (local).
Proof. Consider $\mathcal{S}_{1}$ (global). The only possible $X$ is $\mathbb{P}^{1}$ and if $K+\sum b_{i} B_{i}$ is numerically trivial then $\sum b_{i}=2$. Thus if $\left(b_{i}\right)$ and $\left(b_{i}^{\prime}\right)$ are two sequences of the same length such that $\left(b_{i}\right) \leq\left(b_{i}^{\prime}\right)$ then $\left(b_{i}\right)=\left(b_{i}^{\prime}\right)$. The rest follows by (18.25).
18.26 Corollary. (Dimension three only) Assume that the flip of every special contraction exists.

Then the flip of every limiting contraction also exists.
Proof. Consider all limiting contractions whose flip does not exist. Consider their types. They give a set $\mathcal{B} \subset \overline{\mathcal{S}}_{3}^{0}$ (local). By the ascending chain condition, if $\mathcal{B}$ is not empty, it has a maximal element; let $f:(X, K+S+B) \rightarrow Z$ be a corresponding contraction. By (18.14) the flip of $f$ exists, a contradiction.

# 19. COMPLEMENTS ON LOG SURFACES 

David R. Morrison

One of the key innovations of [Shokurov91] is the notion of $n$-complement, which we now introduce.
19.1 Definition. Let $X$ be a normal variety and let $D$ be a subboundary (2.2.4) on $X$. Let $S$ be the smallest effective Weil divisor on $X$ such that $\llcorner D-S\lrcorner \leq 0$, and let $D_{0}=D-S$. An n-complement of $K_{X}+D$ is a divisor

$$
\bar{D} \in\left|-n K_{X}-n S-\left\llcorner(n+1) D_{0}\right\lrcorner\right|
$$

such that $K_{X}+D^{+}$is $\log$ canonical, where

$$
D^{+}=S+\frac{1}{n}\left(\left\llcorner(n+1) D_{0}\right\lrcorner+\bar{D}\right) .
$$

We say that $K_{X}+D$ is $n$-complemented if an $n$-complement exists.
Note that $n D^{+}$is an integral divisor belonging to the linear system $\left|-n K_{X}\right|$. The defining properties can be formulated as properties of $n D^{+}$, which must satisfy:
(i) $n D^{+}-n S-\left\llcorner(n+1) D_{0}\right\lrcorner$ is effective, and
(ii) $K_{X}+D^{+}$is $\log$ canonical.

We start with some easy properties of $n$-complements.
19.2 Lemma. If $D^{\prime}$ is a subboundary, $D \leq D^{\prime}, K_{X}+D^{\prime}$ is $n$-complemented, then $K_{X}+D$ is $n$-complemented.

If $f: Y \rightarrow X$ is birational, and $K_{X}+D$ is $n$-complemented, then $K_{Y}+f(D)$ is $n$-complemented.
Proof. In the first case, set $D^{+}=\left(D^{\prime}\right)^{+}$, and in the second case, set $f(D)^{+}=$ $f\left(D^{+}\right)$.

We need a generalization of the notion of $n$-complement to cover the case in which the variety $X$ is reducible. There are difficulties formulating this in general, so we restrict our attention to curves and surfaces.
S. M. F.

A variety $X$ is semismooth in codimension 1 if all of its codimension 1 singularities are normal crossing points (cf. (12.2.1)). Such an $X$ is Gorenstein in codimension 1 , so $K_{X}$ exists as a Weil divisor (class). When $\operatorname{dim} X=1$, we call $X$ a semismooth curve. (The usual terminology is nodal curve.)

Let $X$ be a semismooth curve, and let $D=\sum d_{i} D_{i}$ be an $\mathbb{R}$-Weil divisor supported on the smooth locus of $X$. The coefficients $d_{i}$ are allowed to be negative. We say that $K_{X}+D$ is semilog canonical (slc) if $d_{i} \leq 1$. (Since $\operatorname{dim} X=1$, there is no need to take a semiresolution before computing discrepancies. The formula

$$
K_{X}=\left(K_{X}+D\right)+\sum\left(-d_{i}\right) D_{i}
$$

shows that $-d_{i} \geq-1$ is the correct analogue of the lc condition.) Note that $K_{X}+D$ is slc if and only if $D$ is a subboundary whose support lies in the smooth part of $X$.

There is also a definition of semi log canonical in the surface case, originally given in [KSB88], and discussed in (12.2). This definition does require taking semiresolutions. We don't repeat it here.
19.3 Definition. Let $X$ be semismooth in codimension 1 , and let $D$ be a subboundary whose support lies in the smooth part of $X$. Suppose that $\operatorname{dim} X \leq 2$. Let $S$ be the smallest Weil divisor on $X$ such that $\llcorner D-S\lrcorner \leq 0$, and let $D_{0}=D-S$. An $n$-semicomplement of $K_{X}+D$ is a divisor

$$
\bar{D} \in\left|-n K_{X}-n S-\left\llcorner(n+1) D_{0}\right\lrcorner\right|
$$

such that $K_{X}+D^{+}$is slc, where

$$
D^{+}=S+\frac{1}{n}\left(\left\llcorner(n+1) D_{0}\right\lrcorner+\bar{D}\right) .
$$

(The only place where the restriction on dimension enters is in the definition of slc, which has only been given when $\operatorname{dim} X \leq 2$.)

Shokurov's strategy in studying $n$-complements is to use inversion of adjunction (16.13, 17.6) to lift an $n$-complement from $S$ to $X$. For this to be useful, we need an explicit analysis of complements in low dimension.
19.4 Theorem. Let $X$ be a semismooth curve, connected but not necessarily complete, and let $D$ be a subboundary whose support is disjoint from $\operatorname{Sing} X$, and lies in the union of the complete components of $X$. Suppose that $\llcorner D\lrcorner \geq 0$ (so that in particular, $D$ is effective, i.e., is a boundary), and that $-\left(K_{X}+D\right)$ is nef on each complete component of $X$. Then $K_{X}+D$ is 1-, 2-, 3-, 4-, or 6 -semicomplemented.

Moreover, if $K_{X}+D$ is not 1- or 2-semicomplemented, then $X=\mathbb{P}^{1}$ and $\left\llcorner D^{+}\right\lrcorner=0$. In addition, if $X$ contains an incomplete component, and $K_{X}+D$ is not 1 -semicomplemented then $D$ has the form $\frac{1}{2} D_{1}+\frac{1}{2} D_{2}$ for irreducible divisors $D_{1}, D_{2}$.

Proof. The combinatorial ingredients in this proof will seem familiar to those who have studied log canonical surface singularities (cf. Chapter 3), or Kodaira's classification of degenerate elliptic curves. Our proof explicitly gives the divisor $D^{+}$in every case.

Let $C$ be a complete component of $X$, and let $C \cap \operatorname{Sing} X=\left\{P_{1}, \ldots, P_{k}\right\}$. Then $\operatorname{deg}\left(\left.K_{X}\right|_{C}\right)=2 g-2+k$. Since $\operatorname{deg}\left(\left.K_{X}\right|_{C}\right) \leq 0$, there are four possibilities:
(I) $g=1, k=0, \operatorname{deg}\left(\left.K_{X}\right|_{C}\right)=0$
(II) $g=0, k=2, \operatorname{deg}\left(\left.K_{X}\right|_{C}\right)=0$
(III) $g=0, k=1, \operatorname{deg}\left(\left.K_{X}\right|_{C}\right)=-1$
(IV) $g=0, k=0, \operatorname{deg}\left(\left.K_{X}\right|_{C}\right)=-2$.

Now $D$ cannot meet components of type (I) or (II), since $\operatorname{deg}\left(\left.K_{X}\right|_{C}\right)=0$. Since $X$ is connected, if it has a component $C$ of type (I) then $X=C$ and $D=0$. In this case, $K_{X}+D$ is 1-complemented, with $D^{+}=0$.

Components of type (II), however, can meet other components of the same type, and can meet components of type (III) as well. Since there are only two points of intersection on each component of type (II), the entire curve $X$ must form a chain or a cycle. Chains will be terminated by components of type (III), or by incomplete components.

In the case of a cycle, $D$ is again 0 and $K_{X}+D$ is 1 -semicomplemented with $D^{+}=0$. In the case of a chain, any complete component $C$ of type (III) on the end of the chain will have a divisor $D \cap C=\sum d_{i} D_{i}$ with $d_{i} \leq 1$ and $\sum d_{i} \leq 1$. If any $d_{i}=1$, then $D \cap C=D_{1}$ which is 1 -semicomplemented in a neighborhood of $C$ with $D^{+}=D_{1}$. So we may assume $d_{i}<1$. Since $C \cong \mathbb{P}^{1}$, an $n$-complement $\bar{D}$ will exist exactly when its degree $n-\operatorname{deg}\llcorner(n+1)(D \cap C)\lrcorner$ is nonnegative. There are only a few possibilities in this case:
(1) $\llcorner 2 D\lrcorner=0$. Then $K_{X}+D$ is 1 -semicomplemented in a neighborhood of $C$, with $D^{+}=\bar{D}$ for some divisor $\bar{D}$ of degree 1 .
(2) $\llcorner 2 D\lrcorner=D_{1}$. Then $K_{X}+D$ is again 1-semicomplemented in a neighborhood of $C$, with $D^{+}=D_{1}$.
(3) $\llcorner 2 D\lrcorner \geq D_{1}+D_{2}$. This implies that $d_{1}, d_{2} \geq \frac{1}{2}$, and hence that $d_{1}=d_{2}=\frac{1}{2}$. It follows that $\llcorner 3 D\lrcorner=D_{1}+D_{2}$, so that $K_{X}+D$ is 2-semicomplemented in a neighborhood of $C$, with $D^{+}=D \cap C=$ $\frac{1}{2} D_{1}+\frac{1}{2} D_{2}$.
Putting this together from the two ends of the chain, we see that in all cases $K_{X}+D$ must be 1 -semicomplemented or 2 -semicomplemented. In
addition, if there are any incomplete components in $X$ then $K_{X}+D$ is 1semicomplemented unless $D=\frac{1}{2} D_{1}+\frac{1}{2} D_{2}$.

If $X$ has any component of type (IV), that component must be the whole of $X$. So $X \cong \mathbb{P}^{1}$; we write $D=\sum d_{i} D_{i}$ with $1 \geq d_{1} \geq d_{2} \geq \ldots$, and repeatedly use the fact that $\sum d_{i} \leq 2$. If $d_{1}=d_{2}=1$ then $K_{X}+D$ is 1 -complemented with $D^{+}=D_{1}+D_{2}$. If $d_{1}=1>d_{2}$, then $C-\left\{D_{1}\right\}$ has the same numerical properties as a component of type (III). The analysis given above applies to show that $K_{X}+D$ is 1 - or 2 -complemented, with $D^{+}=D_{1}+\widetilde{D^{+}}$, where $\widetilde{D^{+}}$ is the part of $D^{+}$whose support does not contain $D_{1} . \widetilde{D^{+}}$is determined from $\left\llcorner 2\left(D-D_{1}\right)\right\lrcorner$ as in (1), (2), and (3) above.

Thus, we may assume $1>d_{1}$. Then an $n$-complement $\bar{D}$ exists if and only if its degree $2 n-\operatorname{deg}\llcorner(n+1) D\lrcorner$ is nonnegative. The possibilities are:
(1) $\llcorner 2 D\lrcorner=0$. Then $K_{X}+D$ is 1-complemented, with $D^{+}=\bar{D}$ for some divisor $\bar{D}$ of degree 2.
(2) $\llcorner 2 D\lrcorner=D_{1}$. Then $K_{X}+D$ is 1-complemented, with $D^{+}=D_{1}+\bar{D}$ for some divisor $\bar{D}$ of degree 1 .
(3) $\llcorner 2 D\lrcorner=D_{1}+D_{2}$. Then $K_{X}+D$ is 1 -complemented, with $D^{+}=$ $D_{1}+D_{2}$.
(4) $\llcorner 2 D\lrcorner \geq D_{1}+D_{2}+D_{3}$.
(a) $\llcorner 3 D\lrcorner=D_{1}+D_{2}+D_{3}$. Then $K_{X}+D$ is 2-complemented, with $D^{+}=\frac{1}{2} D_{1}+\frac{1}{2} D_{2}+\frac{1}{2} D_{3}+\frac{1}{2} \bar{D}$ for some divisor $\bar{D}$ of degree 1 .
(b) $\llcorner 3 D\lrcorner=D_{1}+D_{2}+D_{3}+D_{4}$. Then $K_{X}+D$ is 2 -complemented, with

$$
D^{+}=\frac{1}{2} D_{1}+\frac{1}{2} D_{2}+\frac{1}{2} D_{3}+\frac{1}{2} D_{4} .
$$

(c) $\llcorner 3 D\lrcorner=2 D_{1}+D_{2}+D_{3}$. Then $K_{X}+D$ is 2 -complemented, with $D^{+}=D_{1}+\frac{1}{2} D_{2}+\frac{1}{2} D_{3}$.
(d) $\llcorner 3 D\lrcorner=2 D_{1}+D_{2}+D_{3}+D_{4}$. This implies that $d_{1}=\frac{2}{3}, d_{2}=$ $d_{3}=\frac{1}{2}, d_{4}=\frac{1}{3}$. Thus, $K_{X}+D$ is 4 -complemented, with $D^{+}=$ $\frac{3}{4} D_{1}+\frac{1}{2} D_{2}+\frac{1}{2} D_{3}+\frac{1}{4} D_{4}$.
(e) $\llcorner 3 D\lrcorner \geq 2 D_{1}+2 D_{2}+D_{3}$.
(i) $\quad\llcorner D\lrcorner=2 D_{1}+2 D_{2}+2 D_{3}$. Then $K_{X}+D$ is 3 -complemented with $D^{+}=\frac{2}{3} D_{1}+\frac{2}{3} D_{2}+\frac{2}{3} D_{3}$.
(ii) $\llcorner 4 D\lrcorner \geq 3 D_{1}+2 D_{2}+2 D_{3}$.
(A) $\llcorner 5 D\lrcorner=3 D_{1}+3 D_{2}+2 D_{3}$. Then $K_{X}+D$ is $4-$ complemented, with $D^{+}=\frac{3}{4} D_{1}+\frac{3}{4} D_{2}+\frac{1}{2} D_{3}$.
(B) $\quad\llcorner 5 D\lrcorner=4 D_{1}+3 D_{2}+2 D_{3}$. In this case, using $\sum d_{i} \leq 2$ one can show that $\llcorner 7 D\lrcorner=5 D_{1}+4 D_{2}+3 D_{3}$. Thus, $K_{X}+D$ is 6 -complemented, with $D^{+}=\frac{5}{6} D_{1}+\frac{2}{3} D_{2}+$ $\frac{1}{2} D_{3}$.
We leave the verification that this covers all possible cases with $\sum d_{i} \leq 2$
to the reader. Here is a sample of the type of argument that is required. Suppose that $\llcorner 2 D\lrcorner \geq D_{1}+D_{2}+D_{3}$ and $\llcorner 3 D\lrcorner \geq 2 D_{1}+2 D_{2}+D_{3}$. Then $d_{1} \geq d_{2} \geq \frac{2}{3}, d_{3} \geq \frac{1}{2}$ so that $\llcorner 4 D\lrcorner \geq 2 D_{1}+2 D_{2}+2 D_{3}$. Furthermore, $d_{4} \leq 2-d_{1}-d_{2}-d_{3} \leq \frac{1}{6}$. Thus, $\left\llcorner 4 d_{i}\right\lrcorner=0$ for $i \geq 4$, and $\llcorner 4 D\lrcorner$ is supported on $D_{1} \cup D_{2} \cup D_{3}$. This justifies the division into cases (i) and (ii).

The last statements in the theorem are clear.
The following corollary is immediate.
19.5 Corollary. Let $D=\sum d_{i} D_{i}$ be a subboundary on $\mathbb{P}^{1}$. Suppose that each $d_{i}$ has the form $d_{i}=\left(m_{i}-1\right) / m_{i}$ for some integer $m_{i}>1$, and that $\operatorname{deg}\left(K_{\mathbb{P}^{1}}+D\right)<0$. Then the integers $m_{i}$ must fall into one of the following cases:
(1) $\left(m_{1}\right)$ or $\left(m_{1}, m_{2}\right)$,
(2) $\left(2,2, m_{3}\right)$,
(3) $(2,3,3)$,
(4) $(2,3,4)$,
(5) $(2,3,5)$.

Moreover, $K_{\mathbb{P}^{1}}+D$ is 1-, 2-, 3-, 4-, or 6-complemented in cases (1), (2), (3), (4), or (5), respectively.

We now begin the analysis which relates complements on $X$ to complements on $S$. The first step can be done in arbitrary dimension.
19.6 Theorem. Let $X$ be a smooth variety, let $Z$ be a normal variety, and let $h: X \rightarrow Z$ be a proper morphism with connected fibers. Let $D=\sum d_{i} D_{i}$ be a $\mathbb{Q}$-subboundary on $X$ (i.e., a subboundary with $d_{i} \in \mathbb{Q}$ ), whose support is a divisor with normal crossings. Assume that $-\left(K_{X}+D\right)$ is $h$-nef and $h$-big.

Write $D=S+D_{0}$ with $S$ the smallest effective Weil divisor such that $\left\llcorner D_{0}\right\lrcorner \leq 0$, and suppose that either $S$ is irreducible, or $\operatorname{dim} X \leq 3$ and $S$ is semismooth in codimension 1. Given an $n$-(semi)-complement $\bar{D}_{S}$ of $K_{S}+$ $\operatorname{Diff}\left(D_{0}\right)$, then in a neighborhood of any fiber of $h$ meeting $S$, there exists a divisor $\bar{D} \in\left|-n K_{X}-n S-\left\llcorner(n+1) D_{0}\right\lrcorner\right|$ such that $\operatorname{Diff}(\bar{D})=\bar{D}_{S}$.

If $K_{X}+S$ is plt or $\operatorname{dim} X \leq 2$ then $\bar{D}$ is an $n$-complement. Moreover, if $K_{S}+\left(D_{S}\right)^{+}$is plt then so is $K_{X}+D^{+}$.

Proof. Divisors from the linear system $\left|-n K_{X}-n S-\left\llcorner(n+1) D_{0}\right\lrcorner\right|$ on $X$ restrict to divisors in the linear system $\left|-n K_{S}-\operatorname{Diff}\left(\left\llcorner(n+1) D_{0}\right\lrcorner\right)\right|$ on $S$, which is the system containing $\bar{D}_{S}$. A failure of surjectivity of the restriction map would be detected by

$$
\begin{aligned}
& R^{1} h_{*}\left(\mathcal{O}_{X}\left(-n K_{X}-(n+1) S-\left\llcorner(n+1) D_{0}\right\lrcorner\right)\right. \\
& \quad=R^{1} h_{*}\left(\mathcal{O}_{X}\left(K_{X}+\left\lceil-(n+1)\left(K_{X}+D\right)\right\rceil\right)\right.
\end{aligned}
$$

But this latter sheaf is 0 by Kawamata-Viehweg vanishing [KMM87,1-2-3]. Thus, the divisor $\bar{D}$ exists in a neighborhood of any fiber of $h$ intersecting $S$.
$K+D^{+}$is lc near $S$ by (17.7). Since $K+D^{+} \equiv 0$, (17.4) shows that $K+D^{+}$is lc in a neighborhood of any fiber of $h$ intersecting $S$.

In order to apply this to surfaces, we need a lemma.
19.7 Lemma. Let $X$ be a smooth surface, let $Z$ be a normal surface, and let $h: X \rightarrow Z$ be a birational morphism. Let $D=\sum d_{i} D_{i}$ be a $\mathbb{Q}$-subboundary on $X$. Assume that
(19.7.1) if $d_{i}<0$ then $h\left(D_{i}\right)$ is a point in $Z$; and
(19.7.2) $-\left(K_{X}+D\right)$ is $h$-nef.

Write $D=S+D_{0}$ with $S$ the smallest effective Weil divisor such that $\left\llcorner D_{0}\right\lrcorner \leq 0$, and suppose that $S$ is a semismooth curve. Then every component of $D_{0}$ which meets $S$ has nonnegative multiplicity in $D_{0}$.

Proof. Write $D_{0}=D_{+}-D_{-}$, with $D_{+}$and $D_{-}$effective such that $\operatorname{Supp}\left(D_{+}\right)$ and $\operatorname{Supp}\left(D_{-}\right)$have no common components. By (19.7.1), $\operatorname{Supp}\left(D_{-}\right)$is contained in the exceptional locus of $h$. If $D_{-} \neq 0$, let $E$ be a component of $D_{-}$with $D_{-} \cdot E>0$. (This exists by negative-definiteness of the intersection matrix of a contractible curve.) Then since $D_{+} \cdot E \geq 0$ and $-\left(K_{X}+S+D_{0}\right)$ is $h$-nef, $\left(K_{X}+S\right) \cdot E<0$. It follows that $E$ is a -1-curve disjoint from $S$. Thus, blowing down $E$ preserves the assumptions of the lemma.

The lemma now follows by induction on the number of components of $\operatorname{Supp}\left(D_{-}\right)$.

We can now apply (19.4) and (19.6) to classify $n$-complements on surfaces.
19.8 Theorem. Let $X$ be a smooth surface, let $Z$ be a normal surface, and let $h: X \rightarrow Z$ be a birational morphism. Let $D=\sum d_{i} D_{i}$ be a $\mathbb{Q}$-subboundary on $X$ whose support is a divisor with normal crossings. Assume that
(19.8.1) if $d_{i}<0$ then $h\left(D_{i}\right)$ is a point in $Z$;
(19.8.2) $-\left(K_{X}+D\right)$ is $h$-nef; and
(19.8.3) $K_{X}+D$ is $\log$ canonical.

Write $D=S+D_{0}$ with $S$ the smallest effective Weil divisor such that $\left\llcorner D_{0}\right\lrcorner \leq 0$, and suppose that $S$ is non-empty. Then $K_{X}+D$ is 1-, 2-, 3-, 4-, or 6-complemented in a neighborhood of a fiber of $h$.

Moreover, if $K_{X}+D$ is not 1- or 2-complemented, then $S=\mathbb{P}^{1}$ and $\left\llcorner D^{+}-\right.$ $S\lrcorner=0$ in a neighborhood of a fiber of $h$. In addition, if there is a component of $S$ which is not contained in a fiber of $h$, and if $K_{X}+D$ is not 1-complemented, then in a neighborhood of any fiber, $\operatorname{Diff}_{S}\left(D_{0}\right)=\frac{1}{2} P_{1}+\frac{1}{2} P_{2}$ for some points $P_{1}, P_{2} \in S$.

Proof. Since $\operatorname{Supp} D$ has normal crossings, $S$ is a semismooth curve. By adjunction (16.9), since $K_{X}+S+D_{0}$ is lc, $K_{S}+$ Diff $D_{0}$ is slc. The normal
crossing assumption implies that $\operatorname{Diff}\left(D_{0}\right)$ is supported on the smooth locus of $S$. Moreover, $-\left(K_{S}+\right.$ Diff $\left.D_{0}\right)$ is nef on every complete component of $S$. By (19.7), ᄂDiff $D_{0\lrcorner}=0$. Thus we may apply (19.4) and conclude that $K_{S}+$ Diff $D_{0}$ is 1-, 2-, 3-, 4-, or 6-semicomplemented and that it is 1- or 2-semicomplemented unless $S=\mathbb{P}^{1}$.

If $\bar{D}_{S}$ is the $n$-semicomplement of $K_{S}+$ Diff $D_{0}$, then by (19.6), in a neighborhood of a fiber of $h$ there is a divisor $\bar{D}$ with $\operatorname{Diff}(\bar{D})=\bar{D}_{S}$ which is an $n$-complement of $K_{X}+D$.

Suppose that $K_{X}+D$ is not 1- or 2-complemented. Then by (19.4), $\left\llcorner D^{+}\right.$ $S\lrcorner=0$ in a neighborhood of $S=\mathbb{P}^{1}$. Let $g: Y \rightarrow X$ be a blowup on which Supp $g^{-1}\left(D^{+}\right)$has normal crossings. Write $K_{Y}=g^{*}\left(K_{X}+D\right)+A-F$ with all multiplicities of components of $A$ being greater than -1 and all multiplicities of components of $F$ being greater than or equal to 1 ; by the connectedness theorem (17.4), $F$ is connected in a neighborhood of a fiber of $h$. But then in that neighborhood, the union of all components of $D^{+}$other than $S$ which have multiplicity 1 in $D^{+}$would necessarily meet $S$. Since $S$ already contains all components of that kind in a neighborhood of itself, there can be no such components.

The last statement follows immediately from (19.4).
19.9 Definition. Let $X$ be a normal variety and let $D$ be a subboundary on $X$. An exceptional $n$-complement of $K_{X}+D$ is an $n$-complement $\bar{D}$ such that there is exactly one divisor $E$ of $\mathbb{C}(X)$ such that $a(E, X, \bar{D})=-1 . K_{X}+D$ is exceptionally $n$-complemented if there exists an exceptional $n$-complement.
19.10 Corollary. Let $X$ and $Z$ be normal surfaces, and let $h: X \rightarrow Z$ be a birational morphism. Let $D=\sum d_{i} D_{i}$ be a $\mathbb{Q}$-subboundary on $X$. Assume that
(19.10.1) if $d_{i}<0$ then $h\left(D_{i}\right)$ is a point in $Z$;
(19.10.2) $-\left(K_{X}+D\right)$ is $h$-nef; and
(19.10.3) $K_{X}+D$ is $\log$ canonical.

Then in a neighborhood of a fiber of $h$, either $K_{X}+D$ is 1 - or 2-complemented, or $K_{X}+D$ is exceptionally 3-, 4-, or 6-complemented.

Proof. Fix $P \in Z$, and let $H$ be a general hyperplane section of $Z$ through $P$. Let $\lambda$ be the largest nonnegative number such that $K_{X}+D+\lambda h^{*}(H)$ is log canonical.

We first replace $D$ by $\widetilde{D}=D+\lambda h^{*}(H)$ and then replace $X$ by a resolution of singularities $g: Y \rightarrow X$ on which the support of the birational transform $\Delta$ of $\widetilde{D}$ has normal crossings. Note that there is at least one component of multiplicity 1 in $\Delta$, for if not one could increase $\lambda$. Thus, we can apply (19.8) to $K_{Y}+\Delta$ and obtain an $n$-complement in a neighborhood of $g^{-1}\left(h^{-1}(P)\right)$.

By (19.2), $D^{+}=g\left(\Delta^{+}\right)$will determine an $n$-complement of $K_{X}+D$ in a neighborhood of $h^{-1}(P)$. Furthermore, if $\left\llcorner\Delta^{+}-S\right\lrcorner=0$ then the induced $n$-complement of $D$ is exceptional. The corollary follows.
19.11 Corollary. Let $X$ and $Z$ be normal surfaces, and let $h: X \rightarrow Z$ be a birational morphism. Let $D=\sum d_{i} D_{i}$ be a $\mathbb{Q}$-subboundary on $X$. Assume that
(19.11.1) if $d_{i}<0$ then $h\left(D_{i}\right)$ is a point in $Z$;
(19.11.2) $-\left(K_{X}+D\right)$ is $h$-ample; and
(19.11.3) $K_{X}+D$ is log terminal.

Suppose in addition that there is a reduced component $S_{0}$ of $D$ not contained in a fiber of $h$. Then in a neighborhood of any fiber of $h$ meeting $S_{0}$, $K_{X}+D$ is 1-complemented.

Proof. We proceed as in the previous proof, replacing $(X, D)$ by $(Y, \Delta)$. Write $\Delta=S+\Delta_{0}$ with $S$ the smallest effective Weil divisor such that $\left\llcorner\Delta_{0}\right\lrcorner \leq 0$. Note that the birational transform of $S_{0}$ is an incomplete component of $S$ in a neighborhood of any fiber of $g \circ h$ which it meets. Since $K_{Y}+\Delta$ is lt and $-\left(K_{Y}+\Delta\right)$ is $(g \circ h)$-ample, we may replace $\Delta$ by $S+(1+\varepsilon) \Delta_{0}$ (for small $\varepsilon>0$ ) without disturbing the assumptions. But now it is impossible for $\operatorname{Diff}\left((1+\varepsilon) \Delta_{0}\right)$ to be $\frac{1}{2} P_{1}+\frac{1}{2} P_{2}$, independent of $\varepsilon$. It then follows from the last statement in (19.8) that $K_{Y}+(1+\varepsilon) \Delta$ (and hence $K_{X}+D$ ) is 1 -complemented.

## 20. COVERING METHOD AND EASY FLIPS

JÁnos Kollár

In this chapter we construct some log flips by reducing their existence to the case of flops. The reduction relies on the following:
20.1 Proposition. Let $f:(C \subset X) \rightarrow(P \in Z)$ be a small contraction of threefolds. Assume that there exists a three dimensional log terminal singularity $0 \in Y$ and a finite morphism $(0 \in Y) \rightarrow(P \in Z)$. Then finite generation holds for $Z$ (4.4). In particular, if $-H$ is an $f$-ample divisor, then the opposite of $f$ with respect to $H$ exists.
Proof. By (4.6) and (6.14) finite generation holds for $Z$. (4.2) gives a small modification $f^{+}: X^{+} \rightarrow Z$ such that $H^{+}$is $f^{+}$-ample. This is the opposite (or flip) of $f$.

Thus the question ahead is to find conditions which ensure that $P \in Z$ is covered by a log terminal point. Such conditions are given after some preparatory remarks about ramified covers.
20.2 Proposition. Let $h: U \rightarrow V$ be a finite and dominant morphism between irreducible normal schemes of characteristic zero. Let $B=\sum b_{i} B_{i}$ be a divisor on $V$ such that $\sum B_{i}$ contains the branch locus of $h$. (We allow $b_{i}=0$, so that the latter condition is easy to satisfy.) Let red $h^{-1}\left(\sum B_{i}\right)=\sum D_{i j}$ where $h\left(D_{i j}\right)=B_{i}$. Let $e_{i j}$ be the ramification index of $h$ at the generic point of $D_{i j}$. Then

$$
h^{*}\left(K_{V}+B\right) \equiv K_{U}+\sum\left(1-\left(1-b_{i}\right) e_{i j}\right) D_{i j} .
$$

Proof. Codimension two subsets do not affect the claim, and hence we may assume that $U, V$ are smooth. There is a natural morphism $h^{*} K_{V} \rightarrow K_{U}$, so that the verification of (20.2) reduces to computing ramifications at the generic point of $D_{i j}$ for every $i, j$. By localizing we are reduced to the case when $U$ and $V$ are one dimensional regular schemes, and this case is straightforward.
S. M. F.
20.3 Proposition. Notation and assumptions as in (20.2). Let $h^{*}\left(K_{V}+\right.$ $B)=K_{U}+\bar{B}$. Then
(20.3.1) $\operatorname{logdiscrep}(U, \bar{B}) \geq \log \operatorname{discrep}(V, B) \geq \frac{1}{\operatorname{deg}(U / V)} \operatorname{logdiscrep}(U, \bar{B})$, and
(20.3.2) $K_{V}+B$ is lc (resp. plt) iff $K_{U}+\bar{B}$ is lc (resp. plt).

Proof. Note first that even if $B$ is effective, $\bar{B}$ is not necessarily so. In the definition of lc and plt (2.10) and (2.13) it is not important that $B$ be effective. We use this more general case in the proof. In most applications however we only use the case when $B$ and $\bar{B}$ are effective.

Let $g: W \rightarrow V$ be a proper modification with $W$ normal (e.g., a resolution of singularities). Let $W_{U}$ be the normalization of $W \times_{V} U$. We have a diagram

Let $D=\sum B_{i}$. We may assume that $g^{-1}$ is an isomorphism outside $D$. Rewriting (2.5) we get that

$$
K_{W}+\operatorname{red} g^{-1}(D) \equiv g^{*}\left(K_{V}+B\right)+\sum a_{\ell}\left(E_{i}, B\right) E_{i},
$$

where $\operatorname{Supp} E_{i} \subset \operatorname{Supp} g^{-1}(D)$. Applying (20.2) to $p: W_{U} \rightarrow W$ we obtain

$$
\begin{aligned}
K_{W_{U}}+\operatorname{red}(g \circ p)^{-1}(D) & \equiv p^{*}\left(K_{W}+\operatorname{red} g^{-1}(D)\right) \\
& \equiv p^{*} g^{*}\left(K_{V}+B\right)+p^{*} \sum a_{\ell}\left(E_{i}, B\right) E_{i} \\
& \equiv g_{U}^{*}\left(K_{U}+\bar{B}\right)+p^{*} \sum a_{\ell}\left(E_{i}, B\right) E_{i}
\end{aligned}
$$

If $p^{*} E_{i}=\sum e_{i j} F_{i j}$ then $a_{\ell}\left(F_{i j}, \bar{B}\right)=e_{i j} a_{\ell}\left(E_{i}, B\right)$.
It is worthwhile to mention the special case when $B=0$ :
20.3.3 Corollary. Let $f: X \rightarrow Y$ be a finite and dominant morphism between normal varieties. Assume that $K_{X}$ and $K_{Y}$ are $\mathbb{Q}$-Cartier. If $X$ is lt (resp. lc) then $Y$ is lt (resp. lc).

For ease of reference we mention three special cases of (20.2-3):
20.4 Corollary. Let $h: U \rightarrow V$ be as in (20.3).
(20.4.1) Assume that $h$ is étale in codimension one. Then $K_{V}+B$ is lc (resp. plt) iff $K_{U}+h^{*} B$ is lc (resp. plt).
(20.4.2) Let $S \subset V$ be the branch locus of $h$ and assume that $B=S+D$. Then $K_{V}+S+D$ is lc (resp. plt) iff $K_{U}+\operatorname{red} h^{-1}(S)+h^{*} D$ is lc (resp. plt).
(20.4.3) Let $S \subset V$ be the branch locus of $h$. Assume that $h$ is a double cover and $B=(1 / 2) S+D$. Then $K_{V}+(1 / 2) S+D$ is lc (resp. plt) iff $K_{U}+h^{*} D$ is lc (resp. plt).
20.5 Proposition. Let $X$ be a normal singularity and $B$ an effective $\mathbb{Q}$ divisor. Assume that $K_{X}+B$ is plt and has index 2 or 1 (i.e. $2(K+B) \sim 0$ ). Then there is a double cover $p: Z \rightarrow X$ such that $Z$ is canonical of index one. If $\operatorname{dim} X=3$ then finite generation holds for every Weil divisor $E$ on $X$.

Proof. Let $D$ be a general member of the linear system $|2 B|$. By Bertini theorems, $D$ is irreducible and reduced. By $(2.33), K+(1 / 2) D$ is plt. Since $2(-K) \sim D$, we can construct a double cover $p: Z \rightarrow X$ which ramifies along $D$. By (20.4.3) $K_{Z}$ is plt. $K_{Z}$ is also Cartier, hence $Z$ is canonical of index one. In dimension three finite generation holds by (20.1).
20.6 Proposition. Let $X$ be a normal singularity and $D$ an effective $\mathbb{Q}$ divisor. Assume that $K_{X}+D$ is lc and has index 2 (or 1). Assume furthermore that $\llcorner D\lrcorner$ is $L S E P D$ and $K+D$ is plt outside $\llcorner D\lrcorner$. Then there is a finite cover $p: Z \rightarrow X$ such that $Z$ is canonical of index one.

If $\operatorname{dim} X=3$ then finite generation holds for every Weil divisor $E$ on $X$.
Proof. The required cover is constructed in two steps. By assumption there is a regular function $s$ such that $\operatorname{Supp}(s=0)=\llcorner D\lrcorner$. Let $(s=0)=\sum m_{i} D_{i}$ and let $m$ be a natural number which is divisible by every $m_{i}$. Let $h: X^{\prime} \rightarrow X$ be the normalization of an irreducible component of $\operatorname{Spec}_{X} \mathcal{O}_{X}[t] /\left(t^{m}-s\right)$. By (20.2)

$$
K_{X^{\prime}}+\operatorname{red} h^{-1}(\llcorner D\lrcorner)+h^{*}\{D\}=h^{*}\left(K_{X}+D\right)
$$

Set $D^{\prime}=\operatorname{red} h^{-1}(\llcorner D\lrcorner)+h^{*}\{D\} .\left(X^{\prime}, D^{\prime}\right)$ has index 2 , is lc and plt outside $\left\llcorner D^{\prime}\right\lrcorner$. Furthermore,

$$
\left\llcorner D^{\prime}\right\lrcorner=\operatorname{red} h^{-1}(\llcorner D\lrcorner)=(t=0)
$$

is Cartier.
Since $2\left(-K-\left\llcorner D^{\prime}\right\lrcorner\right) \sim 2\left\{D^{\prime}\right\}$, we can construct a double cover $p: Z \rightarrow X^{\prime}$ ramified along $\operatorname{Supp}\left\{D^{\prime}\right\}$. By (20.4.3)

$$
K_{Z}+p^{-1}\left(\left\llcorner D^{\prime}\right\lrcorner\right)=K_{Z}+(t \circ p=0)
$$

is Cartier, lc and plt outside $\operatorname{Supp} p^{-1}\left(\left\llcorner D^{\prime}\right\lrcorner\right)$. Thus $K_{Z}$ is also Cartier and plt (2.17), hence $Z$ is canonical of index one. In dimension three the flip of $f$ exists by (20.1).

The following result shows that flips exist if the boundary has at least two components intersecting the flipping curve. Such flips are used repeatedly in Chapters 21 and 22.
20.7 Theorem. Let $X$ be a $\mathbb{Q}$-factorial threefold. Let $D=S+B$ be a $\mathbb{Q}$-divisor, $S$ reduced and $\llcorner B\lrcorner=\emptyset$. Let $f:(C \subset X) \rightarrow(P \in Z)$ be a small contraction with $\rho(X / Z)=1$. Assume that
(20.7.1) $K+D$ is log canonical and numerically nonpositive with respect to $f$;
(20.7.2) $S$ has at least 2 irreducible components $S^{+}$and $S^{-}$meeting $C$ such that $S^{-} \cdot C<0$ and $S^{+} \cdot C>0$.

Then the flip of $f$ exists.
If $C \cdot(K+D)=0$ then strictly speaking we cannot talk about the flip of $f$. However by (4.5) $Z$ has at most one other small, normal and projective modification. By slight abuse of terminology we call it the flip of $f$. It can also be defined as the flip with respect to $K+D-S^{+}$.

The proof is done in several steps. First we prove a weaker version:
20.8 Lemma. Let $X$ be a $\mathbb{Q}$-factorial threefold. Let $D=S+B$ be a $\mathbb{Q}$ divisor, $S$ reduced and $\llcorner B\lrcorner=\emptyset$. Let $f:(C \subset X) \rightarrow(P \in Z)$ be a small contraction with $\rho(X / Z)=1$. Assume that
(20.8.1) $K+D$ is $\log$ terminal and numerically negative with respect to $f$;
(20.8.2) $S$ has at least 2 irreducible components $S^{+}$and $S^{-}$meeting $C$ such that $S^{-} \cdot C<0$ and $S^{+} \cdot C \geq 0$.

Then $K_{X}+D$ is 1-complemented in a neighborhood of $C$ and the flip of $f$ exists.
Proof. First we prove that $K+D$ is 1-complemented. By (17.5) $S^{-}$is normal. By (16.9.2)

$$
K_{S^{-}}+\operatorname{Diff}\left(D-S^{-}\right)=(K+D) \mid S^{-}
$$

is lt and $f$-negative. Assume that $S^{+} \cap S^{-} \subset C$. Then

$$
S^{+} \cdot{ }_{X} C=\left(S^{+} \cap S^{-}\right) \cdot S^{-} C<0
$$

since $C \subset S^{-}$is contractible; a contradiction. Thus there exists an irreducible component of $S^{+} \cap S^{-}$intersecting $C$ but not contained in it. Therefore by (19.11) and (19.6) $K+D$ is 1 -complemented. That is, there exists a reduced divisor $D^{+} \geq\llcorner D\lrcorner$ such that $K+D^{+}$is lc and numerically 0 relative to $f$.

I claim that $D^{+}$is LSEPD. This is clear if $S^{+} \cdot C>0$. If $S^{+} \cdot C=0$ then $C \subset S^{+}$. Since both $S^{-}$and $S^{+}$contain $C$, no other component of $S+B$ can contain $C$, hence they all have nonnegative intersection with $C$. Thus

$$
\left(K+S^{+}+S^{-}\right) \cdot C \leq(K+S+B) \cdot C<0
$$

thus in $D^{+}$there is a component which has positive intersection with $C$.
Let $D_{Z}=f\left(D^{+}\right)$. Then $K_{Z}+D_{Z}$ is $\mathbb{Q}$-Cartier, lc and plt outside $\operatorname{Supp} D_{Z}$. $S^{+}, S^{-} \subset D^{+}$, therefore $D^{+}$and $D_{Z}$ are LSEPD. Thus the flip exists by (20.6).
20.9 Corollary. Let $(X, K+D)$ be a $\mathbb{Q}$-factorial threefold, not necessarily $\log$ canonical. Then in a neighborhood of $S=\llcorner D\lrcorner$ there exists a $\mathbb{Q}$-factorial $\log$ terminal model for $K+D$.
Proof. Let $\left(Y, K_{Y}+D_{Y}\right)$ be a log resolution (where $D_{Y}$ is as in (2.7)) and apply the minimal model program relative to the morphism $f: Y \rightarrow X$ in a neighborhood of $S$. In doing so we might encounter a small contraction

$$
f_{k}: Y_{k} \xrightarrow{g_{k}} Z \rightarrow X
$$

with respect to $K_{Y_{k}}+D_{Y_{k}}$. Let $C$ be the exceptional curve of $g_{k}$. By hypothesis $f_{k}^{*}(S) \cdot C=0$ and $C \subset f_{k}^{*}(S)$. Then $0=f_{k}^{*}(S) \cdot C=\sum c_{i} B_{i} \cdot C$, where the sum is taken over the $i$ such that $B_{i} \cap C \neq \emptyset$. Note that $\sum c_{i} B_{i} \neq 0$, because $C \subset f_{k}^{*}(S)$. This shows that there exists an irreducible component of $\left\llcorner D_{Y_{k}}\right\lrcorner$ meeting $C$ and nef on it.

Let $H$ be an ample divisor on $f_{k}: Y_{k} \rightarrow X$. Then $H=f_{k}^{*} f_{k}(H)-\sum a_{i} E_{i}$ for some $a_{i}>0$ and the $E_{i}$ are exceptional for $f_{k}$. Then $\sum a_{i} E_{i} \cdot C<0$, and thus there exists an index $i$ such that $E_{i} \cdot C<0$. By definition $E_{i} \subset$ $\left\llcorner D_{Y_{k}}\right\lrcorner$. Therefore the flip exists by (20.8) and termination was proved in (7.1). Thus the $\left(K_{Y}+D_{Y}\right)$-MMP terminates and gives the required $\mathbb{Q}$-factorial log terminal model.
20.10 Lemma. Notation and assumptions as in (20.7).
(20.10.1) Assume in addition that $2(K+D) \sim 0$. Then the flip of $f$ exists.
(20.10.2) Assume in addition that $K+D \equiv 0$. Assume furthermore that flips of contractions as in (20.7) exist if $K+D \equiv 0$ and $K+D-S^{+}$is $l$. Then the lip of $f$ exists.

Proof. Let $g:\left(Y, D_{Y}\right) \rightarrow(X, D)$ be a $\mathbb{Q}$-factorial $\log$ terminal model. Let $S_{1}^{+} \subset Y$ be the birational transform of $S^{+}$. By assumption

$$
\begin{aligned}
& 2\left(K_{Y}+D_{Y}\right) \sim g^{*}\left(2\left(K_{X}+D\right)\right) \sim 0 \quad \text { in case } 1, \\
& K_{Y}+D_{Y} \equiv g^{*}\left(K_{X}+D\right) \equiv 0 \quad \text { in case } 2 .
\end{aligned}
$$

By assumption $\llcorner D\lrcorner$ is LSEPD with respect to $f$, thus $\left\llcorner D_{Y}\right\lrcorner$ is LSEPD with respect to $f \circ g$. For $0<\epsilon \ll 1$ apply the $\left(K_{Y}+D_{Y}-\epsilon S_{1}^{+}\right)$-MMP to $(f \circ g): Y \rightarrow Z$. We successively construct objects $h_{k}: Y_{k} \rightarrow Z$ such that
(20.10.3.1) $\left\llcorner D_{Y_{k}}\right\lrcorner$ is LSEPD with respect to $h_{k}$;
(20.10.3.2) $K_{Y_{k}}+D_{Y_{k}}-\epsilon S_{k}^{+}$is lt where $S_{k}^{+} \subset Y_{k}$ be the birational transform of $S^{+}$;
(20.10.3.3)

$$
\begin{array}{r}
2\left(K_{Y_{k}}+D_{Y_{k}}\right) \sim 0 \quad \text { in case } 1 \\
K_{Y_{k}}+D_{Y_{k}} \equiv 0 \quad \text { in case } 2
\end{array}
$$

Assume that in the process we encounter a small contraction $g_{k}: Y_{k} \rightarrow Z_{k}$. Let $C_{k} \subset Y_{k}$ be the flipping curve. Then $C_{k} \cdot S_{k}^{+}>0$, hence $\left\llcorner D_{Y_{k}}\right\lrcorner$ has another irreducible component which intersects $C_{k}$ negatively. Furthermore, by $(20.10 .3 .2) K_{Y_{k}}+D_{Y_{k}}$ is lc, lt outside $\operatorname{Supp}\left\llcorner D_{Y_{k}}\right\lrcorner$ and $K_{Y_{k}}+D_{Y_{k}}-S_{k}^{+}$is lt.

In the first case $K_{Z_{k}}+g_{k}\left(D_{Y_{k}}\right)$ has index two on $Z_{k}$ and is plt outside the LSEPD divisor $\left\llcorner g_{k}\left(D_{Y_{k}}\right)\right\lrcorner$. Thus the flip of $g_{k}$ exists by (20.6). In the second case the flip of $g_{k}$ exists by assumption. By Chapter 7 the sequence of flips terminate. Therefore the program stops with

$$
\bar{h}: \bar{Y} \rightarrow Z
$$

such that $K_{\bar{Y}}+D_{\bar{Y}}-\epsilon \bar{S}^{+}$is $\bar{h}$-nef. (2.32.2) implies that the flip of $f$ with respect to $K_{X}+D-\epsilon S^{+}$exists.

Proof of (20.7). Let $H$ be a sufficiently general and sufficiently $f$-ample divisor. Then for a suitable $1>\epsilon \geq 0, K+D+\epsilon H$ is numerically $f$-trivial and satisfies all the assumptions of (20.7). Thus we may assume that $K+D \equiv 0$. By (20.10.2) it is sufficient to consider the case when in addition $K+D-S^{+}$is lt. As in the proof of $(20.8)$ we see that there exists an irreducible component of $S^{+} \cap S^{-}$intersecting $C$ but not contained in it. Therefore by (19.10) and (19.6) $K+D$ is 1 - or 2 -complemented. Thus by (20.10.1) the flip exists.

The following result applies every time in dimension three when the opposite exists. However in practice it is usually very difficult to find the divisors $S_{i}$ required in the assumptions.
20.11 Theorem. (Mori, unpublished) Let $f: X \rightarrow Z$ be a small morphism with exceptional set $C \subset X$. Let $S_{1}, S_{2} \subset X$ be effective divisors such that $S_{1} \cap S_{2}=C$. Assume that $m_{1} S_{1}$ and $m_{2} S_{2}$ are linearly equivalent for some $m_{1}, m_{2}>0$. Then the opposite of $f$ with respect to $S_{1}$ exists and $S_{1}^{+} \cap S_{2}^{+}=\emptyset$.
Proof. The pencil $\left\langle m_{1} S_{1}, m_{2} S_{2}\right\rangle$ is base point free outside $C$; denote by $p$ : $X \rightarrow \mathbb{P}^{1}$ the corresponding rational map. Then the opposite of $f$ is the normalization of the closure of the image of the map $p \times f: X \rightarrow \mathbb{P}^{1} \times Z$.
20.12 Corollary. Let $f: X \rightarrow Z$ be a small morphism with exceptional set $C \subset X$. Assume that
(20.12.1) $\rho(X / Z)=1$;
(20.12.2) there is a divisor $D$ such that $(X, D)$ is klt and $-\left(K_{X}+D\right)$ is $f$-nef; and
(20.12.3) there are effective divisors $S_{1}, S_{2} \subset X$ such that $S_{1} \cap S_{2}=C$.

Then the opposite of $f$ exists and $S_{1}^{+} \cap S_{2}^{+}=\emptyset$.
Proof.

$$
S_{i} \cdot X=\left(S_{i} \cap S_{3-i}\right) \cdot S_{3-i} C<0
$$

since $C \subset S_{3-i}$ is contractible. Therefore by the base point free theorem [KMM87,3-1-2], suitable positive multiples of $S_{i}$ are linearly equivalent. Thus (20.11) applies.
20.13 Corollary. Let $X$ be a $\mathbb{Q}$-factorial threefold. Let $f:\left(X, K+S_{1}+\right.$ $\left.S_{2}\right) \rightarrow Z$ be a small contraction with $\rho(X / Z)=1$. Assume that $C \cdot\left(K+S_{1}+\right.$ $\left.S_{2}\right)<0, C \cdot S_{1}<0, C \cap S_{2} \neq \emptyset, K+S_{1}+S_{2}$ is lc and $K+S_{1}$ is lt. Then the flip of $f$ exists.

Proof. If $C \cdot S_{2}>0$ then (20.7) applies. If $C \cdot S_{2} \leq 0$ then $C \subset S_{1} \cap S_{2}$. If equality holds then (20.12) applies, otherwise there is a 1 -complement $B$ by (19.11) and we can apply (20.7) with $S^{+}=B$.

## 21. SPECIAL FLIPS

JÁnos Kollár

The aim of the next two chapters is to investigate flips of special contractions (18.8). The importance of these is clear from (18.9). For a special flip $B$ is also reduced, in fact usually it is empty. We change notation and write $S$ for what used to be $S+B$. This is important, since (following Shokurov) from (21.3) on $B$ is used for something different.
21.1 Notation. Let $X$ be a normal $\mathbb{Q}$-factorial threefold and $S \subset X$ an integral Weil divisor. Assume that $K_{X}+S$ is lt. Let $f: X \rightarrow Z$ be a small $(K+S)$ extremal contraction; i.e., $K+S$ is $f$-negative and $\rho(X / Z)=1$. Thus there is a proper curve $C \subset X$ and a finite subset $P \subset Z$ such that $f: X-C \rightarrow Z-P$ is an isomorphism. The existence of flips is local on $Z$; we may pick a point $0 \in P \subset Z$ and assume that $Z$ is a small neighborhood of 0 . Therefore we may assume that $C=f^{-1}(0)$ is connected, but in general $C$ may be reducible.

We assume that $C \cdot S_{i}<0$ for every irreducible component $S_{i} \subset S$. In particular, every $S_{i}$ contains $C$.

We call $f:(X, S) \rightarrow Z$ a special contraction. By a slight abuse of language, the flip of $f$ is called a special flip.

Our aim is to construct the flip of $f$. This is done in several steps. First we construct the flip in certain special cases. For the remaining cases, we prove that they exist provided index two flips exist. Index two flips turn out to be the hardest, they are discussed in the next chapter.
21.2 Proposition. If $S$ is reducible, the flip exists.

Proof. As we remarked, $C \subset S_{i}$ for every $i$. Since $K+S$ is lt, $S_{1} \cap S_{2}$ is a locally irreducible curve (16.9). Thus $S_{1} \cap S_{2}=C$ (and $C$ is irreducible). Thus the flip exists by (20.12).
21.2.1 Convention. For the rest of the chapter we always assume that $S$ is irreducible.
21.3 Definition. Assumptions as above.
S. M. F.
(21.3.1) By (19.6,19.8) there is an $n \in\{1,2,3,4,6\}$, called the index of $K+S$, such that $K+S$ is $n$-complemented. I.e. there is a $\mathbb{Q}$-divisor $B$ such that $n B$ is an integral divisor, $K+S+B$ is lc and $n(K+S+B) \sim 0$. (This $B$ has nothing to do with the $B$ occurring in the definitions (18.1-8).)
(21.3.2) We say that $K+S+B$ is exceptional if ( $S$, $\operatorname{Diff}_{S}(B)$ ) is exceptional in the sense of (19.9). Observe that this may depend on the choice of $B$. Sometimes the contraction $f$ itself is called exceptional if the choice of $B$ is already agreed upon. The same applies to the flip of $f$.
21.4 Proposition. Index one flips exist.

Proof. Index one means that $B$ is an integral Weil divisor. Since

$$
C \cdot B=-C \cdot(K+S)>0
$$

$S+B$ and $f(S+B)$ are reduced LSEPD divisors, and the flip exists by (20.7).
21.5 Proposition. If $K+S+B$ has index two and $K+S+B$ is lt, then the flip exists.
Proof. Assume first that $\llcorner B\lrcorner \neq \emptyset$ and let $S^{\prime} \subset\llcorner B\lrcorner$. If $C \cdot S^{\prime}>0$ then the flip exists by (20.7). If $C \cdot S^{\prime} \leq 0$ then $C \cdot\left(K+S+S^{\prime}\right) \leq C \cdot(K+S)<0$; the flip exists by (20.13). If $\llcorner B\lrcorner=\emptyset$ then $K+S+B$ is plt by (2.16.3) hence (20.5) gives the flip.

Next we apply the Backtracking Method (6.4-5). The notation and conventions of (6.4-5) are used throughout.
21.6 Construction of $q_{1}: Y_{1} \rightarrow X_{0}$. Assume that $K+S+B$ is not lt. Let $h: X^{t} \rightarrow X$ be a $\mathbb{Q}$-factorial lt model (20.9). By assumption $h$ is not an isomorphism. If $E^{t} \subset X^{t}$ is the reduced exceptional divisor then $K_{X^{t}}+E^{t}+$ $S^{t}+B^{t}=h^{*}(K+S+B)$ is lt.
21.6.1 Lemma. For any irreducible component $E \subset E^{t}$ there is a unique projective morphism $q_{1}: Y_{1} \rightarrow X_{0}$ with the following properties
(21.6.1.1) $Y_{1}$ is $\mathbb{Q}$-factorial and $\rho\left(Y_{1} / X\right)=1$.
(21.6.1.2) The exceptional set of $q_{1}$ is an irreducible divisor $E_{1} \subset Y_{1}$ such that under the birational map $Y_{1} \rightarrow X \leftarrow X^{t}$ the birational transform of $E_{1}$ is $E$.
(21.6.1.3) $q_{1}$ is a log crepant morphism, i.e.

$$
K+E_{1}+S_{1}+B_{1}=q_{1}^{*}(K+S+B)
$$

and is lc.
Proof. Uniqueness of $Y_{1}$ follows from (6.2).

The existence follows from the $\left(K_{X^{t}}+E^{t}+S^{t}+B^{t}-\epsilon E\right)$-MMP applied to $X^{t} \rightarrow X$. We need to check that all flips exist and any sequence of them terminates. Let $C \subset X^{t}$ be a flipping curve. Since $K_{X^{t}}+E^{t}+S^{t}+B^{t}$ is numerically $h$-trivial, $C \cdot E>0$. As in the proof of (20.9) we find another exceptional divisor $E_{k}$ such that $C \cdot E_{k}<0$. Thus the flip exists by (20.7) and termination follows from (7.1).

At the end we obtain a morphism $q^{\prime}: Y^{\prime} \rightarrow X$ and $E^{\prime} \subset Y^{\prime}$, which is the birational transform of $E$. Furthermore,

$$
-\epsilon E^{\prime} \equiv K_{Y_{1}}+\left(E^{t}+S^{t}+B^{t}\right)^{\prime}-\epsilon E^{\prime}
$$

is $q^{\prime}$-nef. $\operatorname{Supp}\left(E^{t}+S^{t}+B^{t}\right)^{\prime}=\operatorname{Supp} q^{\prime *}(S+B)$ is LSEPD with respect to $q^{\prime}$, hence base point freeness applies to $-E^{\prime}(2.32 .2)$. Thus we obtain a morphism

$$
Y^{\prime} \xrightarrow{r} Y_{1} \xrightarrow{q_{1}} X,
$$

such that $-E_{1}$ (the birational transform of $-E^{\prime}$ ) is $q_{1}$-ample. Thus $E_{1}$ contains the exceptional set of $q_{1}$. If $D$ is a Weil divisor on $Y_{1}$ then $D=$ $q_{1}^{*}\left(q_{1}(D)\right)+c(D) E_{1}$ for some $c(D) \in \mathbb{Q}$, and hence $Y_{1}$ is $\mathbb{Q}$-factorial.

From now on we always assume that $q_{1}: Y_{1} \rightarrow X_{0}$ is chosen as in (21.6.1).
21.6.2 Lemma. Notation as in (6.4).
(21.6.2.1) $K+S_{j}+E_{j}+B_{j}$ is lc for every $j$;
(21.6.2.2) There are $c_{e}, c_{b}>0$ such that $S_{j}+c_{e} E_{j}+c_{b} B_{j}$ is numerically trivial on $Y_{j} / Z$ for every $j$.

Proof. By (21.6.1.3) the first part holds for $j=1$. Since $S \cdot C<0$ and $B \cdot C>0$, there is a $c_{b}>0$ such that $\left(S+c_{b} B\right) \cdot C=0$. Let $S_{1}+c_{e} E_{1}+c_{b} B_{1}=q_{1}^{*}\left(S+c_{b} B\right)$. Both of these properties are stable under flips and flops.

### 21.7 Existence of the contractions $r_{i}$.

Choose $0 \leq a_{b}<1$ such that the coefficient of $E_{1}$ in $q_{1}^{*}\left(K_{X}+S+a_{b} B\right)=$ $K+S_{1}+a_{b} B_{1}+a_{e}^{\prime} E_{1}$ is positive.
21.7.1 Proposition. Assume that $1>a_{e}>a_{e}^{\prime}$ is sufficiently close to $a_{e}^{\prime}$. Then
(21.7.1.1) $R_{j} \cdot\left(K+S_{j}+a_{b} B_{j}+a_{e} E_{j}\right)<0$ for every $j$.
(21.7.1.2) $K+S_{j}+a_{b} B_{j}+a_{e} E_{j}$ is plt for every $j$.
(21.7.1.3) $R_{j}$ can be contracted.
(21.7.1.4) There are $b_{s}, b_{e}>0$ such that $R_{j} \cdot\left(b_{s} S_{j}+b_{e} E_{j}\right)<0$ for every $j$. Proof. (6.5.2) proves (21.7.1.1).

By assumption $K_{X}+S$ is plt. Since $q_{1}$ is an isomorphism outside $E_{1}$, this implies that $K+S_{1}$ is plt outside $E_{1} \cup B_{1}$. By (21.6.2.1) $K+S_{1}+E_{1}+B_{1}$
is lc, thus $K+S_{1}+a_{b} B_{1}+a_{e} E_{1}$ is plt along $E_{1} \cup B_{1}$ since $a_{b}, a_{e}<1$. Thus $K+S_{1}+a_{b} B_{1}+a_{e} E_{1}$ is plt. By (21.7.1.1) plt is preserved under flips. The first two claims imply the third.

Both $K+S+a_{b} B$ and $S$ are negative on $C$, thus $K+S+a_{b} B \equiv c S$ for some $c>0$. Thus

$$
\begin{aligned}
K+S_{1}+a_{b} B_{1}+a_{e} E_{1} & \equiv q_{1}^{*}\left(K+S+a_{b} B\right)+\left(a_{e}-a_{e}^{\prime}\right) E_{1} \\
& \equiv q_{1}^{*}(c S)+\left(a_{e}-a_{e}^{\prime}\right) E_{1} \equiv b_{s} S_{1}+b_{e} E_{1}
\end{aligned}
$$

for some $b_{s}, b_{e}>0$. This equivalence is preserved by subsequent flips.
Another useful general result is the following:
21.7.2 Lemma. Notation as above. Then either $R_{j} \cdot S_{j}>0$ or $Q_{j} \cdot S_{j}>0$.

Proof. $S_{j}$ intersects the exceptional set but does not contain it. Thus $S_{j}$ cannot be seminegative on $Y_{j} / Z$.

### 21.8 Three Kinds of Flips of the Backtracking Method.

The sequence of flips in the backtracking method can be broken into three parts. Some easy flips in the beginning, some hard flip (hopefully at most one) in the middle and then again a sequence of easy flips. (Any of these may be empty in a given situation.)

### 21.8.1 Beginning Flips.

In the first step $Q_{1} \cdot E_{1}<0$. If $R_{1} \cdot E_{1} \leq 0$ then there is no beginning flip. In general however $R_{1} \cdot E_{1}>0$. Assume more generally that $R_{i-1} \cdot E_{i-1}>0$. Then $Q_{i} \cdot E_{i}<0$. If $R_{i} \cdot E_{i} \leq 0$ then the beginning sequence is finished. If $R_{i} \cdot E_{i}>0$ then $R_{i} \cdot S_{i}<0$ since by (21.7.1.4) $R_{i} \cdot\left(b_{s} S_{i}+b_{e} E_{i}\right)<0$. Thus the contracted curve is contained in $S_{i}$ and intersects $E_{i}$. The flip of $r_{i}$ exists by (21.6.2.1) and (20.7). Since the flipping curve is contained in $S_{i}$, the beginning sequence of flips terminates (7.1). Thus we eventually get a divisorial contraction (and we are finished) or reach $E_{m} \subset Y_{m}$ such that $E_{m}$ is seminegative on $Y_{m} / Z$. Therefore $E_{m}$ contains every $Y_{m} / Z$-exceptional curve.

### 21.8.2 Middle Flips.

The flipping of $r_{m}: Y_{m} \rightarrow X_{m}$ is the hardest step. We distinguish several cases. We use Locus $\left(R_{m}\right)$ to denote the exceptional set of $r_{m}$.
(21.8.2.1) $\operatorname{Locus}\left(R_{m}\right)=S_{m} \cap E_{m}$.

The flip exists by (20.11) and $S_{m+1}$ and $E_{m+1}$ are disjoint. Since $E_{m}$ contains every $Y_{m} / Z$-exceptional curve, $S_{m} \cap E_{m} \subset S_{m}$ is the only $S_{m} \rightarrow f(S)$ exceptional curve. Thus $S_{m+1}$ does not contain any exceptional curves, hence $S_{m+1}$ is nef relative to $Y_{m+1} \rightarrow Z . Q_{m+1} \cdot S_{m+1}>0$, so that $R_{m+1} \cdot S_{m+1}=0$,
and therefore $r_{m+1}: Y_{m+1} \rightarrow X_{m+1}$ contracts $E_{m+1}$. Thus $X_{m+1}$ is the flip of $f$. We are finished.
(21.8.2.2) Locus $\left(R_{m}\right)$ is a proper subset of $S_{m} \cap E_{m}$.

I do not know any useful general result in this case. An important special case is treated in [Shokurov91, 6.11].
(21.8.2.3) Locus $\left(R_{m}\right)$ is disjoint from $S_{m}$.

In this case we need to argue that ( $r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}$ ) is in some sense "simpler" than ( $f: X \rightarrow Z, K+S+B$ ) and use induction. Assume that $r_{m}$ can be flipped. Then $Q_{m+1} \cdot S_{m+1}=0$. By (21.7.2) $R_{m+1} \cdot S_{m+1}>0$.
(21.8.2.4) $R_{m} \cdot S_{m}>0$. This belongs to the next case.

### 21.8.3 Final Flips.

These are the flips of type (21.8.2.4) or any flip following a flip of type (21.8.2.3-4).
21.8.3.1 Lemma. Assume that $R_{j} \cdot S_{j}>0$. Then $R_{j} \cdot E_{j}<0$, the flip of $r_{j}$ exists and $R_{j+1} \cdot S_{j+1}>0$.
Proof. $R_{j} \cdot E_{j}<0$ follows from (21.7.1.4). The flip of $r_{j}$ exists by (20.7).
By assumption $Q_{j+1} \cdot S_{j+1}<0$. Thus $R_{j+1} \cdot S_{j+1}>0$ by (21.7.2).
21.8.3.2 Corollary. Final flips exist and terminate.

First we give an easy application of the backtracking method.
21.9 Proposition. Assume that $K_{X}+S+B$ is not lt outside Supp $S$. Then the flip exists.

Proof. Assume first that $\llcorner B\lrcorner$ is not empty. Let $E$ be an irreducible component of $\llcorner B\lrcorner$. If $E \cdot C>0$ then (20.7) applies. Thus assume that $E \cdot C \leq 0$. Then

$$
(K+S+E) \cdot C \leq(K+S) \cdot C<0,
$$

and therefore the ( $K+S+E$ )-flip exists by (20.13).
If $\llcorner B\lrcorner=\emptyset$ then there is an irreducible curve $D \subset X$, not contained in $S$ such that $K+S+B$ is not lt along $D$. Let $h: X^{t} \rightarrow X$ be a $\mathbb{Q}$-factorial lt model of $(X, K+S+B)$ in a neighborhood of $S$. This exists by (20.9). By assumption there is an exceptional divisor $E \subset X^{t}$ such that $h(E)=D$. Using $E$ construct $q_{1}: Y_{1} \rightarrow X_{0}$ as in (21.6). Assume that we already constructed $r_{i}: Y_{i} \rightarrow X_{i}$. Using (21.6.2.1) the following claim implies that $r_{i}$ can be flipped:
21.9.1 Claim. If $r_{i}$ is small then $E_{i}$ intersects every curve in the extremal ray $R_{i}$ and $R_{i} \cdot S_{i}<0$.

Proof. Let $P_{1}, P_{2}$ be the two extremal rays. $Y_{i} \rightarrow Z$ maps $E_{i}$ to $f(D)$. Let $F_{i} \subset E_{i}$ be a general fiber of $E_{i} \rightarrow f(D)$. Then $F_{i} \cdot E_{i}<0$. We can specialize
$F_{i}$ to the central fiber to conclude that $E_{i}$ is negative on at least one of the extremal rays of $\overline{N E}\left(Y_{i} / Z\right)$, say $P_{1} \cdot E_{i}<0$. If $E_{i}$ contains the whole exceptional set $U$ of $Y_{i} / Z$ then $E_{i}$ intersects every exceptional curve. $U$ is connected, so if $U \not \subset E_{i}$ then there is a curve $D \subset U$ such that $D \cdot E_{i}>0$. In this case necessarily $P_{2} \cdot E_{i}>0$, thus $E_{i}$ intersects every curve in $P_{2}$ as well.
$R_{i} \cdot S_{i}<0$ is proved by induction. First let $i=1$ and let $D$ be a curve in $R_{1}$. Then $q_{1}(D)$ is an irreducible component of $C$, and hence

$$
S_{1} \cdot D=q_{1}^{*} S \cdot D=S \cdot q_{1}(D)<0
$$

Assume now that $R_{i-1} \cdot S_{i-1}<0$. Then $Q_{i} \cdot S_{i}>0$. Thus if $R_{i} \cdot S_{i} \geq 0$ then $S_{i}$ is $Y_{i} / Z$-nef. $Y_{i}$ is $\mathbb{Q}$-factorial, hence $S_{i} \cap E_{i} \subset E_{i}$ is a divisor which lies entirely in the central fiber of $E_{i} / f(D)$. Therefore it can not be nef unless it is empty. If $S_{i} \cap E_{i}=\emptyset$ and $S_{i}$ is $Y_{i} / Z$-nef then $S_{i} \cdot R_{i}=0$ and $r_{i}: Y_{i} \rightarrow X_{i}$ contracts the whole divisor $E_{i}$.

If $E_{i} \cdot R_{i}>0$ then the flip of $r_{i}$ exists by (20.7). Otherwise $E_{i} \cdot R_{i} \leq 0$, hence by (21.6.2.2) $R_{i} \cdot B_{i}>0$. Thus $\left(K+S_{i}+E_{i}\right) \cdot R_{i}<0$ and the flip of $r_{i}$ exists by (20.13).

The above claim also implies that the exceptional locus of $r_{i}$ is contained in $S_{i}$, and hence the sequence of flips terminates by (7.1).

The second application of the backtracking method requires more delicate considerations.
21.10 Theorem. Assume that index two special flips exist. Then all special flips exist.

Using (19.6) and (19.8) this is a direct consequence of two propositions (21.12-13) whose formulation requires a definition:
21.11 Definition. Consider an extremal contraction with $K+S+B$ of index $n$. For certain values of $s \geq 1$ we can write

$$
B=\sum_{i=1}^{s} \frac{1}{n} B^{i}
$$

where the $B^{i}$ are nonzero effective integral Weil divisors and $C \cdot B^{i} \geq 0$. One such way is $B=(1 / n)(n B)$, but there may be others. The maximum value of $s$ for which this is possible is called the type of $(f: X \rightarrow Z, K+S+B)$. (This has nothing to do with the type defined in (18.2) and no confusion is possible.)
21.12 Proposition. Fix $n$ and $t \geq 1$. Assume that index $n$ exceptional special flips of type at least $t$ exist whenever $K+S+B$ is lt. Then all exceptional special flips of index $n$ and type $t$ exist.
21.12.1 Corollary. Index 2 exceptional special flips exist.

Proof. By (21.5) index two flips exist if $K+S+B$ is lt.
The following is a reformulation of [Shokurov91,7.4]. The proof is a case by case analysis.
21.13 Proposition. Let $(f: X \rightarrow Z, K+S+B)$ be an exceptional special contraction of index $n$ and type $t$ such that $K+S+B$ is lt. Then one can find a $B^{\prime}$ such that one of the following holds:
(21.13.1) $K+S+B^{\prime}$ has index 1 or 2 ;
(21.13.2) $\left(f: X \rightarrow Z, K+S+B^{\prime}\right)$ is an exceptional special contraction of index $n^{\prime}$ and type $t^{\prime}$ and in the following diagram $\left(n^{\prime}, t^{\prime}\right)$ lies to the right of $(n, t)$.

$$
\begin{aligned}
(6, \geq 1) \rightarrow(4, \geq 1) & \rightarrow(6,2) \rightarrow(6, \geq 3) \rightarrow \\
& \rightarrow(3, \geq 1) \rightarrow(4,2) \rightarrow(4,3) \rightarrow(4, \geq 4)
\end{aligned}
$$

21.14 Proof of (21.12). Let $(f: X \rightarrow Z, K+S+B)$ be an exceptional special contraction of index $n$ and type $t$. If it is lt, there is nothing to prove. Otherwise let $h: X^{t} \rightarrow X$ be a $\mathbb{Q}$-factorial lt model with exceptional divisor $E^{t} \subset X^{t}$. The proof proceeds by induction on the number of irreducible components of $E^{t}$. To be more precise, we consider the minimum of the number of irreducible components of $E_{i}^{t}$ where $h_{i}: X_{i}^{t} \rightarrow X$ runs through all $\mathbb{Q}$-factorial lt models. (Usually there are infinitely many.) We call this number the minimal number of log crepant divisors. In what follows we let $h: X^{t} \rightarrow X$ be a $\mathbb{Q}$-factorial lt model where the minimum is achieved.

If $f\left(E^{t}\right) \not \subset S$ then the flip exists by (21.9). Thus assume from now on that $f\left(E^{t}\right) \subset S$. Let $S^{t}\left(\right.$ resp. $\left.B^{t}\right)$ be the birational transform of $S$ (resp. B) on $X^{t}$. Then

$$
\left(h \mid S^{t}\right)^{*}(K+S+B \mid S)=h^{*}(K+S+B)\left|S^{t}=K_{X^{t}}+S^{t}+E^{t}+B^{t}\right| S^{t} .
$$

Since $f$ is exceptional, $K+S+B \mid S$ is exceptional, and therefore on $S^{t}$ there is at most one curve with $\log$ discrepancy zero. Every curve in $E^{t} \cap S^{t}$ appears with log discrepancy zero, hence $E^{t} \cap S^{t}$ is an irreducible curve. Thus there is a unique component $E \subset E^{t}$ which intersects $S^{t}$ and $D=E \cap S^{t}$ is an irreducible curve. By (21.6), $E$ determines $q_{1}: Y_{1} \rightarrow X$. However, we need a direct construction of $Y_{1}$ which provides additional information.
21.14.1 Claim. $S^{t}$ is $h$-nef.

Proof. The only curve where this may fail is $D$. If $h(D)$ is a curve then we do not have to consider $D$. Thus assume that $h(D)$ is a point (this is the typical
case). Let $H$ be a sufficiently ample divisor on $X$ disjoint from $h(D) . D$ is the only curve with the property that $D \cdot S^{t}<0$, thus $[D]$ is an extremal ray. Since $D=E \cap S^{t}$, the flip exists by (20.13). After the flip $\left(S^{t}\right)^{+}$becomes nef relative to $h^{+}:\left(X^{t}\right)^{+} \rightarrow X$. Furthermore $\left(S^{t}\right)^{+}$and $\left(E^{t}\right)^{+}$are disjoint. Applying base point freeness to $\left(S^{t}\right)^{+}(2.32 .2)$ we obtain a morphism

$$
\left(X^{t}\right)^{+} \xrightarrow{p} U \xrightarrow{s} X
$$

where $p$ contracts $\left(E^{t}\right)^{+}$. Thus $s: U \rightarrow X$ is small. $s$ is not an isomorphism since

$$
D^{+} \cdot\left(S^{t}\right)^{+}>0
$$

hence $p\left(D^{+}\right) \subset U$ is a curve contracted by $s$. Since $X$ is $\mathbb{Q}$-factorial, this is impossible.
21.14.2 Construction of $q_{1}: Y_{1} \rightarrow X$. Since $S^{t}$ is $h$-nef, we can apply base point freeness to obtain

$$
X^{t} \xrightarrow{p} Y_{1} \xrightarrow{q_{1}} X .
$$

$p$ contracts $E^{t}-E$, thus $q_{1}$ has at most one exceptional divisor, the image of $E$. There is a curve $A \subset E$ such that $h(A)$ is a point and $A$ intersects $S^{t}$ positively. Thus $p(A)$ is not contracted by $q_{1}$. Since $X$ is $\mathbb{Q}$-factorial, $q_{1}$ is not small, thus $E_{1}=p(E)$ is the exceptional divisor of $q_{1}$.

Let $W_{1} \subset Y_{1}$ denote the closed subset where $p^{-1}$ is not defined. By construction $W_{1} \cap S_{1}=\emptyset$. Since

$$
K+S^{t}+E^{t}+B^{t}=p^{*}\left(K+S_{1}+E_{1}+B_{1}\right)
$$

we see that $K+S_{1}+E_{1}+B_{1}$ is lt outside $W_{1} \cdot p: X^{t} \rightarrow Y_{1}$ is a $\mathbb{Q}$-factorial lt model which has one fewer exceptional divisors than $h: X^{t} \rightarrow X$.

### 21.14.3 Applying the Backtracking Method.

21.14.3.1 Claim. Suppose that $i \leq m$ (i.e., we performed only beginning flips). Then
(21.14.3.1.1) $Y_{1} \rightarrow Y_{i}$ is an isomorphism in a neighborhood of $W_{1}$. Let $W_{i} \subset Y_{i}$ be the image of $W_{1}$.
(21.14.3.1.2) $K+S_{i}+E_{i}+B_{i}$ is plt outside $W_{i}$ and the generic point of $S_{i} \cap E_{i}$.
Proof. By construction $K+S_{1}+E_{1}+B_{1}$ is lt outside $W_{1}$. Therefore it is plt outside the generic point of $S_{1} \cap E_{1}$ since there are no triple intersections. Assume that the claim holds for $i-1$. Let $D_{i-1} \subset Y_{i-1}$ be the locus of $R_{i-1}$. As we showed in (21.8.1), $D_{i-1} \subset S_{i-1}$ and $D_{i-1} \cdot E_{i-1}>0$. Therefore

$$
D_{i-1} \cap W_{i-1} \subset S_{i-1} \cap W_{i-1}=\emptyset
$$

Therefore $Y_{i-1} \rightarrow Y_{i}$ is an isomorphism in a neighborhood of $W_{i-1}$ and (21.14.3.1.1) is clear.
$S_{i-1} \cap E_{i-1}$ is a contractible curve in $S_{i-1}$, hence

$$
\left(S_{i-1} \cap E_{i-1}\right) \cdot E_{i-1}<0
$$

Therefore $D_{i-1} \not \subset E_{i-1}$ and so $K+S_{i-1}+E_{i-1}+B_{i-1}$ is plt along $D_{i-1}$. Therefore $K+S_{i}+E_{i}+B_{i}$ is plt along $D_{i-1}^{+}$which proves (21.14.3.1.2) for $i$.

Now consider middle flips. (21.8.2.1) finishes the backtracking method. (21.8.2.2) is impossible since $S_{m} \cap E_{m}$ is irreducible by (21.14.3.1.2).

In case (21.8.2.3) the flip of $r_{m}$ is provided by induction in view of the following:

### 21.14.3.2 Claim.

(21.14.3.2.1) $\left(r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}\right)$ has the same index as ( $f:$ $X \rightarrow Z, K+S+B)$.
(21.14.3.2.2) The type of $\left(r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}\right)$ is not smaller than the type of $(f: X \rightarrow Z, K+S+B)$.
(21.14.3.2.3) The minimal number of $\log$ crepant divisors of $\left(r_{m}: Y_{m} \rightarrow\right.$ $\left.X_{m}, K+E_{m}+B_{m}\right)$ is smaller than the minimal number of $\log$ crepant divisors of $(f: X \rightarrow Z, K+S+B)$.
(21.14.3.2.4) $\left(r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}\right)$ is either lt or an exceptional special neighborhood.
Proof. By definition of index, $n\left(K_{X}+S+B\right)$ is a principal divisor. Thus $n\left(K+S_{1}+E_{1}+B_{1}\right)=q_{1}^{*} n\left(K_{X}+S+B\right)$ is also a principal divisor. This property is preserved under flips, and hence $n\left(K+S_{m}+E_{m}+B_{m}\right)$ is a principal divisor. Since $S_{m}$ is disjoint from $\operatorname{Locus}\left(R_{m}\right), n\left(K+E_{m}+B_{m}\right)$ is a principal divisor in a neighborhood of $\operatorname{Locus}\left(R_{m}\right)$.

Let $B=\sum_{i}(1 / n) B^{i}$ be the decomposition giving the type. Since $C \cdot B^{i} \geq 0$, there is an $s^{i} \geq 0$ such that

$$
C \cdot\left(s^{i} S+B^{i}\right)=0
$$

Pulling it back to $Y_{1}$, we obtain positive numbers $e^{i}$ such that

$$
s^{i} S_{1}+e^{i} E_{1}+B_{1}^{i}
$$

is numerically trivial on $Y_{1} / Z$. This property is preserved by flips, and therefore

$$
s^{i} S_{m}+e^{i} E_{m}+B_{m}^{i}
$$

is numerically trivial on $Y_{m} / Z$. Since $D_{m}$ is disjoint from $S_{m}$ and $D_{m} \cdot E_{m}<0$, we conclude that $D_{m} \cdot B_{m}^{i}>0$ for every $i$. Thus

$$
B_{m}=\sum \frac{1}{n} B_{m}^{i}
$$

shows that the type of $\left(r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}\right)$ is at least as large as the type of $(f: X \rightarrow Z, K+S+B)$.

Let $W_{i} \subset U_{i} \subset Y_{i}(i=1, m)$ be open neighborhoods such that $Y_{m} \rightarrow Y_{1}$ is an isomorphism between $U_{m}$ and $U_{1}$. Then patching $Y_{m}-W_{m}$ and $p^{-1}\left(U_{1}\right) \subset$ $X^{t}$ gives a $\mathbb{Q}$-factorial lt model of $Y_{m}$ with one less crepant divisors than in $X^{t} \rightarrow X$.

We still need to show that ( $r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}$ ) is exceptional. Let $F^{\prime}=E_{m}$ and let $K_{F^{\prime}}+D^{\prime}=\operatorname{Diff}\left(K+E_{m}+B_{m}\right)$. Then $K+D^{\prime}$ is lc. Let $b$ : $F \rightarrow F^{\prime}$ be a $\log$ terminal model and $K_{F}+D=b^{*}\left(K_{F^{\prime}}+D^{\prime}\right)$. If $K+E_{m}+B_{m}$ is lt along $\operatorname{Locus}\left(R_{m}\right)$ then there is nothing to prove. Otherwise $\llcorner D\lrcorner$ has at least two connected components: one is the birational transform of $S_{m} \cap E_{m}$ and the other lives over Locus $\left(R_{m}\right)$. Thus $\left(r_{m}: Y_{m} \rightarrow X_{m}, K+E_{m}+B_{m}\right)$ is either lt or exceptional by (12.3.2).

After the middle flip, we have only final flips left, and these always exist by (21.8.3.2).

## 22. INDEX TWO FLIPS

Tie Luo

In this chapter we outline some of the steps of Shokurov's proof of the existence of log-flips in the case where $f: C \subset X \rightarrow 0 \in Z$ is a special nonexceptional index 2 extremal contraction. The proof given in [Shokurov 92] is long (about 35 pages) and we can not claim to have understood all of it.

The assumptions are:
(22.1.1) $K+S+B$ is lc and $2(K+S+B) \sim 0$ in a neighborhood of $C$;
(22.1.2) $S \cdot C<0$;
(22.1.3) $K+S$ is plt and $X$ is $\mathbb{Q}$-factorial;
(22.1.4) $(K+S) \cdot C<0$;
(22.1.5) $K+S+B$ is nonexceptional in a neighborhood of $C$ (by (21.12.1));
(22.1.6) $K+S+B$ is lt outside Supp $S$ (by (21.9));
(22.1.7) there is a unique irreducible component $L \subset\left\llcorner\operatorname{Diff}_{S}(B)\right\lrcorner$ which is not contained in $C$ (this follows from (22.2)).
22.2 Lemma. (22.2.1) Assume that all index two flips satisfying (22.1.1-7) exist. Then all index two flips satisfying (22.1.1-6) exist.
(22.2.2) Assume that $f: X \rightarrow Z$ satisfies (22.1.1-6) and $\left\llcorner\operatorname{Diff}_{S}(B)\right\lrcorner \not \subset C$. Pick a component $L \subset\left\llcorner\operatorname{Diff}_{S}(B)\right\lrcorner$ which is not in $C$. Let $L^{c} \subset \operatorname{Supp}^{(i f f}{ }_{S}(B)$ be the connected component of $\operatorname{Supp} \operatorname{Diff}_{S}(B)$ containing $L$. If $L^{c}$ contains another noncontracted curve then $(X, S)$ is 1-complemented, and the flip exists.

Proof. The first part is essentially the statement that if we apply the backtracking method to an arbirtary index two flip then the middle flip satisfies (22.1.7), (21.9) or else it is exceptional.

In case (22.2.2) it is easy to see that one can find an effective divisor $M$ such that $M$ is $f$-nef and $\operatorname{Supp} M=\operatorname{Supp} L^{c}-L$. Thus $(S, \operatorname{Diff}(B)-\epsilon M)$ satisfies the assumptions of (19.11). Hence ( $S$, $\operatorname{Diff}(B)-\epsilon M$ ) is 1-complemented, and therefore so is $(S, \operatorname{Diff}(\emptyset))$.
S. M. F.
22.3 Further subdivison of cases. By passing to the analytic category we may assume that our flipping curve $C$ is irreducible. We consider four types of extremal contractions. These four cases exhaust all possibilities if $C$ is irreducible, but not if $C$ is reducible. Because of certain technical details of the inductive proof, in case (22.3.c) we allow the flipping curve to be reducible.
(22.3.a) $C$ is irreducible and $C \not \subset \operatorname{Supp}(B)$. In particular, $K+S+B$ is lt at the generic point of $C$;
(22.3.b') $C$ is irreducible, $K+S+B$ is not lt along $C$ and there is a point $Q \notin L$ such that $(S, \operatorname{Diff}(B))$ is not lt at $Q$. In this case $C \subset \operatorname{Supp}(B)$.
(22.3.b ${ }^{\prime \prime}$ ) $C$ is irreducible, $K+S+B$ is not lt along $C$ and $(S, \operatorname{Diff}(B))$ is lt outside $L$. In this case $C \subset \operatorname{Supp}(B)$;
(22.3.c) $C$ is possibly reducible, $K+S+B$ is lt at every generic point of $C$ and $C \subset \operatorname{Supp}(B)$.

The proof of the existence of flips proceeds by induction on two numbers: the height of a Shokurov flower and the S-log difficulty. These are defined shortly.
22.4 Definition - Proposition. Assume that $X$ is lt and $(X, S)$ is lc. By (6.6) there are only finitely many exceptional divisors $E$ such that discrep $(E, X) \leq$ 0 . We define the $S$-log difficulty of $(X, S)$ (denoted by $\delta(X, S)$ or simply by $\delta)$ to be the number of exceptional divisors $E$ such that

$$
\begin{equation*}
\operatorname{discrep}(E, X) \leq 0 \quad \text { and } \quad \operatorname{discrep}(E, X, S)=-1 \tag{22.4.1}
\end{equation*}
$$

If $f: Y \rightarrow X$ is a proper birational morphism then set $f^{*} S=f_{*}^{-1}(S)+$ $\sum d\left(E_{i}\right) E_{i}$. By definition $d\left(E_{i}\right)=\operatorname{discrep}\left(E_{i}, X, B\right)-\operatorname{discrep}\left(E_{i}, X, S+B\right)$. Thus (22.4.1) can be rewritten as

$$
\begin{equation*}
d(E) \leq 1 \quad \text { and } \quad \operatorname{discrep}(E, X, S+B)=-1 \tag{22.4.2}
\end{equation*}
$$

22.5 Definition. An extremal contraction $g: Y \rightarrow X$ is a good extraction if it is $\log$ crepant and satisfies the following conditions:
(22.5.1) $K+S+E$ is lt;
(22.5.2) $D=S \cap E \cong \mathbb{P}^{1} ;($ By (22.5.1) $S$ and $E$ cross normally generically along $D$.)
(22.5.3) For double adjunctions, we have

$$
\operatorname{Diff}_{D}\left(\operatorname{Diff}_{S}(E+B)\right)=\operatorname{Diff}_{D}\left(\operatorname{Diff}_{E}(S+B)\right)=\frac{1}{2} P_{1}+\frac{1}{2} P_{2}+P
$$

where $P$ is the unique non-lt point for $K+S+B+E$ on $D$.
22.6 Lemma. There is a finite chain of good extremal extractions in cases (22.3.a) and (22.3.b") such that in the last extraction there is only one non-lt point (as $P$ in (22.5.3)) on the exceptional divisor.
Proof. In either case the boundary of $K_{S}+$ Diff $(B)$ has exactly one component passing through the non-lt point. We construct the chain inductively. Taking a lt model for $K+S+B, h: X^{t} \rightarrow X$, we apply the $\left(K^{t}+S^{t}+B^{t}+E^{t}-\epsilon B^{t}\right)$ MMP. Along the way back to $X$, there is a flip or divisorial contraction, after which we get the neighborhood of $Q=C \cap L$ in case (a) $(Q \in C \neq C \cap L$ in case $\left(\mathrm{b}^{\prime \prime}\right)$ ). This step is not a flip since the modifications are done over $X$. So it is a divisorial contraction. It must be a contraction of $E$ to the point $Q$ because the non-exceptional assumption. Let us call the contraction $g_{1}:\left(X_{1}, E_{1}=E\right) \rightarrow\left(X_{0}=X, Q\right) . g_{1}$ is log-crepant and $K+g_{1}^{-1} S+E$ is lt by assumptions. It implies that $g_{1}^{-1} S$ and $E$ cross normally and $E \cap\left(g_{1}\right)_{*}^{-1} S \cong \mathbb{P}^{1}$. Also

$$
\left(K+\left(g_{1}\right)_{*}^{-1} S+E+\left(g_{1}\right)_{*}^{-1} B \mid g_{1}^{-1} S\right) \left\lvert\, E \cap\left(g_{1}\right)_{*}^{-1} S=K_{\mathbb{P}^{1}}+\frac{1}{2} P_{1}+\frac{1}{2} P_{2}+P\right.
$$

where $P=\left(g_{1}\right)_{*}^{-1} S \cap E \cap\left(g_{1}\right)_{*}^{-1} L . g_{1}$ is a good extraction. Assume that we have constructed a chain of good extractions that starts at $X$ and ends with:

$$
g_{i}:\left(X_{i}, E_{i}\right) \rightarrow\left(X_{i-1}, Q_{i-1} \in E_{i-1}\right)
$$

We are done if there is no non-lt point on $E_{i}$ except along $E_{i} \cap\left(g_{i}\right)_{*}^{-1} E_{i-1}$. Otherwise let $Q_{i}$ be the non-lt point. There is an irreducible $L_{i}$ from the reduced part of $g^{*}(K+S+B) \mid E_{i}$ (where $g$ is the composite of all the $g_{i}$ ). $Q_{i} \in$ $L_{i}$. Moreover $L_{i}$ is the only locus where $g_{*}^{-1} B$ intersects $E_{i}$ in a neighborhood of $Q_{i}$. Looking again from the $\mathbb{Q}$-factorial lt model $X^{t}$ using $\left(K^{t}+S^{t}+B^{t}+\right.$ $\left.E^{t}-\epsilon B^{t}\right)$-MMP, we claim that the last step of the modification that gives the neighborhood of $Q_{i}$ is a divisorial contraction to $Q_{i}$. We show that this step cannot be a flip. Let $C^{\prime}$ be the flipped curve passing $Q_{i}$. By assumption $C^{\prime} \cdot g_{*}^{-1} B<0 . g^{*} B \cdot C^{\prime}=0$ implies that there is an exceptional divisor $E^{\prime}$ such that $E^{\prime} \cdot C^{\prime}>0$. There is no exceptional locus passing through $Q_{i}$ and $g_{i}^{*} E_{i-1} \cdot C^{\prime}=0, C^{\prime} \cdot\left(g_{i}\right)_{*}^{-1} E_{i-1}<0$.

So $C^{\prime}$ lies in $\left(g_{i}\right)_{*}^{-1} E_{i-1}$.

$$
\operatorname{Diff}_{\left(g_{i}\right)_{*}^{-1} E_{i-1}}\left(\left(g_{i}\right)_{*}^{-1} B+E_{i}\right)
$$

is not klt along $E^{\prime} \mid\left(g_{i}\right)_{*}^{-1} E_{i-1}$ and at $Q_{i}$. Hence by (12.3.1) it is not lt along $C^{\prime} . K+\left(g_{i}\right)_{*}^{-1} E_{i-1}+E_{i}$ is lt before the flip and $K+\left(g_{i}\right)_{*}^{-1} E_{i-1}+\left(g_{i}\right)_{*}^{-1} B+E_{i}$ is not lt in the neighborhood of the flipping curve. Therefore $\left(g_{i}\right)_{*}^{-1} B$ intersects
$E_{i}$ more than $L_{i}$ around $Q_{i}$. This is a contradiction. The nonexceptional assumption prevents the modification being a contraction to a curve. So this modification is a divisorial contraction to $Q_{i}$. We check as before that it is a good contraction. The process stops after finitely many steps since the number of exceptional divisors in the lt model is finite.

The above lemma justifies the following:
22.7 Definition. We define the minimum number of good extremal extractions needed in the lemma the height of the Shokurov flower, and denote it by $\lambda$.

We remark that the above construction does not work in the cases (22.3.b') and (22.3.c) since condition (22.5.3) for a good extraction would fail.
22.8 Proposition. For the cases (22.3.b') and (22.3.c) we have the following: (22.8.1) either there is a good extraction of $g:(Y, E) \rightarrow(X, C)$ such that $d(E) \leq 1$;
(22.8.2) or the flip of $f$ exists.

Comments. This formulation (taken from [Shokurov92, 8.8]) does not make much sense since a posteriori flips always exist. The claim is that if the construction given in [ibid, 8.8] fails to yield a good extraction then the end result of the construction can be used to produce the flip.

The original version [Shokurov91, 8.8] claimed that one always has the first case. It is not clear if the second case is really necessary.

The following easy lemma (whose proof is left to the reader) is used repeatedly in the proof of the final theorem.
22.9 Lemma. Let $f: S \rightarrow T$ be a birational map between normal surfaces and $D$ an effective ample divisor on $S$. If $f^{-1}(\operatorname{Supp}(D))$ is irreducible then $f^{-1}(\operatorname{Supp}(D))$ is nef.

The attached flow chart at the end of this chapter outlines the proof of the last theorem. Here $g: Y \rightarrow X$ is a good extraction as constructed for the cases (22.3. $\left.\mathrm{a}, \mathrm{b}^{\prime}, \mathrm{b}^{\prime \prime}, \mathrm{c}\right)$. The flow chart ignores the possibility that at some step we ended up in case (22.8.2), when the flip is known to exist.
22.10 Theorem. Index two flips exists.

Proof. As we remarked earlier, we may assume that all the assumptions of (22.1) are satisfied and we need to consider only the cases (22.3.a, $\left.\mathrm{b}^{\prime}, \mathrm{b}^{\prime \prime}, \mathrm{c}\right)$.

We reduce the existence of the required flip to that of the exceptional cases when either $\lambda$ or $\delta$ is zero, for which the result is known.

Let $g: Y \rightarrow X$ be the good extraction according to cases (22.3.a-c). (If a good extraction does not exist then the flip exists by (22.8).) We have $\rho(Y / Z)=2$. There are two extremal rays, and $R_{1}$ corresponds to $g$. The
contraction of $R_{2}$ is small. We consider the first flip accordingly. In the following we identify $L$ and $S$ with their birational transforms on $Y$ and $D=S \cap E$.

Assume $f$ is of case (22.3.a). On $Y$ the locus of $R_{2}$ is $C$, the proper trasform of $C$ in $X . E \cdot R_{2}>0$ and $S \cdot R_{2}<0$. The first flip exists by (20.7). If $P=D \cap L$ is not on $C, K+S+B+E$ is lt in a neighborhood of $C$. After the flip, on $X_{1}, K+S_{1}+B_{1}+E_{1}$ is lt around the flipped $C^{+}$in $E_{1}$. Let $R_{2}$ be the new flipping ray on $X_{1}$. The locus $C_{1}$ of $R_{2}$ is in $E_{1}$. As in (21.8) we treat only the case where $C_{1}$ is apart from $S_{1}$ and $K+S_{1}+B_{1}+E_{1}$ is not plt along $C_{1}$. Otherwise the existence of flip is known and is followed by a divisorial contraction to $X^{+}$, the required flip of $f$. When that is so, since

$$
D_{1}=E_{1} \cap S_{1} \subset\left\llcorner\operatorname{Diff}_{E_{1}}\left(S_{1}+B_{1}\right)\right\lrcorner,
$$

there is an $L^{\prime} \subset\left\llcorner\operatorname{Diff}_{E_{1}}\left(S_{1}+B_{1}\right)\right\lrcorner$ not in $C_{1}$ intersecting $C_{1}$ at a point $Q$ and $D_{1}$ at $P^{+}$. This implies $L^{\prime}$ irreducible. $\operatorname{Supp}\left(B_{1}\right)$ does not contain $C_{1}$. If $C_{1}$ were reducible, we contract an irreducible component of $C_{1}$ and then take an extremal ray $R$ of $E_{1}$ (after contraction of a component of $C_{1}$ ) such that $R \cdot D_{1}>0$. Notice that $L^{\prime}$ becomes ample by (22.9). The existence of such a ray is guaranteed by $\left(D_{1}\right)^{2}>0$. If cont ${ }_{R}$ contracts a curve $F$ then (12.3.1) forces

$$
F \cap D_{1} \cap L^{\prime}=P^{+}
$$

By induction on $\rho\left(E_{1}\right)$, we may assume that $\operatorname{cont}_{R}$ is of fiber type over a curve after all because $C_{1} \cap D_{1}=\emptyset$. By (12.3.1) $\operatorname{Diff}_{E_{1}}\left(S_{1}+B_{1}\right)$ has only $P^{+}=$ $L^{\prime} \cap D_{1}$ as non-plt point on $L^{\prime}$ which contradicts our starting assumption. So $C_{1}$ is irreducible. This technique is used later. We are again in Case (22.3.a) with smaller $\lambda$. If $P \in C$, we have $R_{2} \cdot E>0, R_{2} \cdot B>0$ and $R_{2} \cdot S<0$. The flip in $C$ exists by (20.7). $C^{+} \subset E_{1} \cap \operatorname{Supp}\left(B_{1}\right)$. As before we consider only the case where the locus $C_{1}$ of the new flipping curve $R_{2}$ is away from $S_{1}$ and $\left(K+S_{1}+B_{1}+E_{1}\right) \mid E_{1}$ has LCS along $C_{1}$. It implies the flipped $C^{+}$is irreducible and $C^{+} \cap D_{1}=P^{+}$, which is the only point where $B_{1}$ passes $D_{1}$. So

$$
S_{1} \cdot\left(\operatorname{Supp}\left(B_{1} \mid E_{1}\right)-C^{+}\right)=0
$$

It means $\operatorname{Supp}\left(B_{1} \mid E_{1}\right)-C^{+}$is in $C_{1}$. In fact they are equal, for otherwise we contract $\operatorname{Supp}\left(B_{1} \mid E_{1}\right)-C^{+}$in $C_{1}, C^{+}$becomes ample by (22.9). We use the same method as we did in the first part by looking at contractions on $E_{1}$ to get a contradiction. If $K+S_{1}+B_{1}+E_{1}$ is lt along $C_{1}$ we go to case (22.3.c). Otherwise $C_{1}$ has to be irreducible and we have case (22.3.b').

Let $f$ be of case (22.3.b'). Let $C$ be the locus of $R_{2}$. If $C=D=S \cap E$. The flip in $C$ exists and $S$ and $E$ are separated. It is followed by a divisorial contraction of $E^{+}$. We are done. Otherwise $C \cap S=\emptyset$. We treat only the
case when $K+S+B+E$ has LCS along $C$. Then there is an irreducible $L^{\prime}$ as a fiber of $g$ in $E, L^{\prime} \cap D=P$ and $L^{\prime} \cap C_{1}=Q . P$ is the only point where $B$ intersects $D$. That is to say

$$
S \cdot\left(\operatorname{Supp}(B \mid E)-L^{\prime}\right)=0
$$

It implies $\operatorname{Supp}(B \mid E)-L^{\prime}$ is in $C$. If we contract $\operatorname{Supp}(B \mid E)-L^{\prime}, L^{\prime}$ becomes ample. As before

$$
\operatorname{Supp}(B \mid E)-L^{\prime}=C
$$

If $K+S+B+E$ is lt along $C$ we are in case (22.3.c). Otherwise $C$ is irreducible and we are in case (22.3. $\mathrm{b}^{\prime}$ ) with smaller $\delta$.
$f$ is in case (22.3.b"). The locus of $R_{2}$ is $C . E \cdot R_{2}>0$ and $S \cdot R_{2}<0$. The flip to $X_{1}$ in $C$ exists by (20.7). By the proof of (22.8) we may consider only the case when $D_{1}=S_{1} \cap E_{1}$ is irreducible. The locus $C_{1}$ of the new flipping ray $R_{2}$ is away from $S_{1}$. We treat only the case when $K+S_{1}+B_{1}+E_{1}$ is not lt along $C_{1}$. There is an irreducible $L^{\prime} \subset\left\llcorner\operatorname{Diff}_{E_{1}}\left(S_{1}+B_{1}\right)\right\lrcorner$ such that $L^{\prime} \cap D_{1}=P$ and $L^{\prime} \cap C_{1}=Q$. Indeed $L^{\prime}=C^{+} . P$ is the only point where $B_{1}$ intersects $D_{1}$. We check as before that

$$
\operatorname{Supp}\left(B_{1} \mid E_{1}\right)-L^{\prime}=C_{1}
$$

If $K+S_{1}+B_{1}+E_{1}$ is lt along $C_{1}$ we are in case (22.3.c). Otherwise $C_{1}$ is irreducible and we are in case (22.3.b').

If $f$ is of case (22.3.c). The locus $C$ of $R_{2}$ may not be connected. $D=E \cap S$ is irreducible. $P=L \cap D$. If $C$ has components passing through $P_{1}, P_{2}$ on $D$, $K+S+B+E$ is lt in neighborhoods of those components. Hence the flips in these curves exist. After the flips on $X_{1}$ we may assume $P^{+}=L_{1} \cap D_{1}$ is the only point on $D_{1}$ where $B_{1}$ intersects $D_{1}$. We consider only the case when the locus $C_{1}$ of the new flipping ray $R_{2}$ is away from $S_{1}$ and $K+S_{1}+B_{1}+E_{1}$ is not lt along $C_{1}$. Then there is an $L^{\prime} \subset\left\llcorner\operatorname{Diff}_{E_{1}}\left(S_{1}+B_{1}\right)\right\lrcorner$ such that $L^{\prime} \cap D_{1}=P^{+}$ and $L^{\prime} \cap C_{1}=Q$, the non-lt point on $C_{1}$. As before, we can check that

$$
\operatorname{Supp}\left(B_{1} \mid E_{1}\right)-L^{\prime}=C_{1}
$$

$K+S_{1}+B_{1}+E_{1}$ is klt at some point of $C_{1}$. We are in the case (22.3.c) with smaller $\delta$.

This is the end of the induction.
The flowchart ignores easy flips and (22.8.2) outcome of the procedure.

## The Flow Chart

# 23. UNIRATIONALITY OF THE GENERAL COMPLETE INTERSECTION OF SMALL MULTIDEGREE 

Kapil H. Paranjape and V. Srinivas

It is well-known that a quadric hypersurface with a rational point is rational. Similarly, a cubic hypersurface of dimension at least two is unirational once it contains a rational line; over an algebraically closed field this latter condition is always satisfied. These results were generalized by [Morin40], who showed that the general hypersurface of degree $d$ and dimension sufficiently large is unirational once it contains a linear space of sufficiently large dimension defined over the given field; this latter condition being always true over an algebraically closed field. This was further generalized by [Predonzan49] to include the case of complete intersections.

The papers [Morin40,Predonzan49] are quite hard to locate and the only easily available account is in the book of [Roth55], where one finds a sketch of the proof for the result of Morin. Analysing this proof it is easy to recover a proof of the result of Predonzan. We present here a proof of these results and some related results. After this paper was written we came to know of a recent paper [Ramero90] where the bounds obtained by Predonzan have been improved.
23.1 An illustrative example. We illustrate the proof in the general case by showing how to deduce the unirationality of a general quartic of sufficiently large dimension using as inductive starting point the following well known
23.1.1 Fact. A smooth cubic hypersurface $X \subset \mathbb{P}_{k}^{n}$ of dimension at least two ( $n \geq 3$ ) which contains a line $P_{k}^{1} \subset X \subset \mathbb{P}_{k}^{n}$, is unirational over $k$.

The proof is in several steps.
(23.1.2). We choose $n$ sufficiently large so that a general quartic hypersurface in $\mathbb{P}_{k}^{n}$ contains a linear subspace $\mathbb{P}_{k}^{3}$ (this choice of dimension is dictated by the ambient dimension for the case of cubics), for $k$ an algebraically closed field.

To do this consider the incidence locus

where $G=G\left(\mathbb{P}^{3}, \mathbb{P}^{n}\right)$ is the Grassmanian, $\mathbb{P}^{N}$ is the space of all quartic hypersurfaces in $\mathbb{P}^{n}$ and $Z$ consists of pairs $(L, X)$, with $L \cong \mathbb{P}^{3} \subset \mathbb{P}^{n}$ a linear subspace contained in a quartic hypersurface $X$. Then $Z$ is a projective subbundle of $G \times \mathbb{P}^{n}$ of codimension $\binom{3+4}{4}=35$. Hence, if

$$
(\operatorname{dim} G=) \quad(n-3)(3+1) \geq 35
$$

then $\operatorname{dim} Z \geq \operatorname{dim} \mathbb{P}^{N}$; so that we can expect the map $Z \rightarrow \mathbb{P}^{N}$ to be surjective. This is the case as shown in (23.2.3). Now in $X$ is a point of $\mathbb{P}^{N}$, we can find a point of $Z$ lying over it if $k$ is algebraically closed.
(23.1.3). Assume that we have a general pair $(L, X)$ in $Z$ defined over some field $k$ (not neccessarily algebraically closed). The collection of all $\mathbb{P}^{4}$ which contain $L \cong \mathbb{P}_{k}^{3}$ form a $\mathbb{P}_{k}^{n-4}$. The intersection $\mathbb{P}^{4} \cap X$ is the union of $\mathbb{P}_{k}^{3}$ and $Y \subset \mathbb{P}^{4}$, which is a cubic hypersurface. Moreover $Y \cap \mathbb{P}^{3}$ is a cubic surface.

Let $\tilde{X}_{L} \rightarrow X$ be the blow up of $X$ along $L$ and let $E$ be the exceptional divisor. We have a natural map $\tilde{X}_{L} \rightarrow \mathbb{P}_{k}^{n-4}$ which is a fibration by cubic hypersurfaces. Moreover, we have a natural diagram

which makes the map $E \rightarrow \mathbb{P}_{k}^{n-4}$ a fibration by cubic surfaces.
Let $G^{\prime}=G\left(\mathbb{P}_{k}^{1}, \mathbb{P}_{k}^{3}\right)$ be the Grassmannian of lines in $\mathbb{P}^{3}$ and let $I \subset G^{\prime} \times$ $\mathbb{P}_{k}^{n-4}$ be the incidence locus of pairs $(M, t)$ such that the fibre of $E$ over $t$ contains the line $M$. We already know that $I$ dominates $\mathbb{P}_{k}^{n-4}$ so suppose that
there is a component of $I$ that dominates $\mathbb{P}^{n-4}$ and is rational over $k$.
Let $K$ be the function field of this component and ( $M, t$ ) the corresponding point of $I$. Then $t$ is a generic point of $\mathbb{P}_{k}^{n-4}$ and $M$ is contained in the fibre $E_{t}$ of $E$ over $t \in \mathbb{P}^{n-4}$. Thus, $M$ is contained in the fibre $Y_{t}$ of $\tilde{X}_{L}$ over $t \in \mathbb{P}^{n-4}$, making $Y_{t}$ a cubic hypersurface of dimension three which contains
a line. Thus $Y_{t}$ is unirational over $K$ by induction. Now in the Cartesian diagram

$$
\begin{array}{rll}
Y_{t} & \hookrightarrow & \tilde{X}_{L} \\
\downarrow & & \downarrow \\
\operatorname{Spec} K & \hookrightarrow & \mathbb{P}_{k}^{n-4}
\end{array}
$$

the horizontal arrows are dominant and so the unirationality of $Y_{t}$ over $K$ and the rationality over $k$ of $K$ imply that $\tilde{X}_{L}$ is unirational over $k$.

In order to ensure that condition (23.1.4) holds we note that if $I \rightarrow G^{\prime}$ is dominant, then the generic fibre of this map is a linear projective subspace of $\mathbb{P}^{n-4}$; in particular, this generic fibre is rational over $k$. Thus in order to complete the inductive argument we must choose our $n$ in step one so that $Z \rightarrow G$ is also dominant. This is achieved by the condition (23.2.4) below.
23.2 Linear spaces in Complete Intersections. Let $\mathbf{d}=\left(d_{1}, \ldots, d_{r}\right)$ be an $r$ tuple of positive integers, and $n, k$ be any positive integers such that one of the following conditions hold:
(23.2.1) If $r=1$ and $d=2$ then $n>2 k$.
(23.2.2) If $r>1$ or there is $i$ with $d_{i}>2$, and $d_{i}>1$ for all $i$, then

$$
(n-k)(k+1) \geq \sum_{i=1}^{r}\binom{k+d_{i}}{d_{i}}
$$

23.2.3 Lemma. Let $n, k, d_{1}, \ldots, d_{r}$ be positive integers satisfying one of the conditions above. Let $H_{i}$ be hypersurfaces of degree $d_{i}$ in $\mathbb{P}^{n}$. There is a linear subspace $\mathbb{P}^{k} \subset \mathbb{P}^{n}$ which is contained in the intersection of all the $H_{i}$.
Proof. Let $V=\Gamma\left(\mathbb{P}^{n}, \mathcal{O}_{\mathbb{P}^{n}}(1)\right)$ and $G$ be the Grassmannian of linear subspaces of dimension $k$ in $\mathbb{P}^{n}=\mathbb{P}(V)$. We have the universal short exact sequence

$$
0 \rightarrow S \rightarrow V \times G \rightarrow Q \rightarrow 0
$$

of vector bundles on $G$, where $Q$ is of rank $k+1$. This yields a filtration on $\operatorname{Sym}^{d_{i}}(V) \times G$ such that

$$
\left(F^{0} / F^{1}\right)\left(\operatorname{Sym}^{d_{i}}(V) \times G\right)=\operatorname{Sym}^{d_{i}}(Q)
$$

and we have a surjection

$$
D_{i}: F^{1}\left(\operatorname{Sym}^{d_{i}}(V) \times G\right) \rightarrow S \otimes \operatorname{Sym}^{d_{i}-1}(Q)
$$

The incidence locus

$$
Z=\left\{\left(F_{1}, \ldots, F_{r}, L\right) \in\left(\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(V)\right) \times G \mid F_{i} \text { vanishes on } L, \text { for all } i\right\}
$$

can alternatively be described as the direct sum

$$
Z=\oplus_{i=1}^{r} F^{1}\left(\operatorname{Sym}^{d_{i}}(V) \times G\right) .
$$

We need to show that the projection $\pi: Z \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(V)$ is surjective. If we knew that the top Chern class of $\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q)$ is nonzero this would follow easily, but there seems to be no direct way of proving this nonvanishing statement.

For each point $z=(\mathbf{F}, L)$ in $Z$ we have a linear inclusion of the fibre $Z_{L}$ of $Z \rightarrow G$ at $L$, into $\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(V)$. Thus, in order to show the surjectivity of $d \pi$ at $z$ it is enough to show the surjectivity of the induced map

$$
\psi_{z}: T_{G, L}=T_{Z, z} / Z_{L} \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}\left(Q_{L}\right)=\left(\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(V)\right) / Z_{L}
$$

Writing $T_{G, L}=S_{L}^{*} \otimes Q_{L}$ we check that the $\psi_{z}$ is the composite

$$
S_{L}^{*} \otimes Q_{L} \xrightarrow{\phi_{z} \otimes \mathrm{Id}} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(Q_{L}\right) \otimes Q_{L} \xrightarrow{\text { product }} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}\left(Q_{L}\right)
$$

where $\phi_{z}$ is the map induced by the image of $z$ under the map

$$
\oplus D_{i}: Z \rightarrow S \otimes \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q) .
$$

Since the product homomorphism is surjective we would have surjectivity of $\psi_{z}$ if we knew the surjectivity of $\phi_{z}$. This in turn would follow for a suitable choice of $z$ if we have the stronger condition

$$
\begin{equation*}
\operatorname{dim} S_{L}=n-k \geq \sum_{i=1}^{r}\binom{k+d_{i}-1}{d_{i}-1} \tag{23.2.4}
\end{equation*}
$$

Once we have the surjectivity of $d \pi$ at some $z$, we get that $\pi$ is dominant. Since $G$ is complete, $\pi$ is proper and thus we get surjectivity of $\pi$ as required.

Since we need the lemma only for the stronger hypothesis (23.2.4) we defer the proof of the general cases (23.2.1-2) to (23.6).
23.3 Definition. We define, by induction on the positive integers $r, d_{1}, \ldots, d_{r}$, the positive integers $n\left(d_{1}, \ldots, d_{r}\right)$ and $k\left(d_{1}, \ldots, d_{r}\right)$ as follows
(23.3.1) If $r=1$ and $d_{1}=1$ then $n(1)=1$ and $k(1)=0$.
(23.3.2) If $r>1, d_{i}=1$ for some $i$ and $\mathbf{d}^{\prime}=\left(d_{1}, \ldots, d_{i-1}, d_{i+1}, \ldots, d_{r}\right)$, then we define $n(\mathbf{d})=n\left(\mathbf{d}^{\prime}\right)+1$ and $k(\mathbf{d})=k\left(\mathbf{d}^{\prime}\right)$
(23.3.3) If $d_{i}>1$ for all $i$, let $\mathbf{d}-\mathbf{1}=\left(d_{1}-1, \ldots, d_{r}-1\right)$. We define $k(\mathbf{d})=n(\mathbf{d}-\mathbf{1})$ and

$$
n(\mathbf{d})=k(\mathbf{d})+\sum_{i=1}^{r}\binom{k(\mathbf{d})+d_{i}-1}{d_{i}-1}
$$

Note that we obtain the inequality

$$
n(\mathbf{d})-k(\mathbf{d}) \geq \sum_{i=1}^{r}\binom{k(\mathbf{d})+d_{i}-1}{d_{i}-1}
$$

in all of the above cases, i.e. (23.2.4) is always satisfied if we take $n \geq n(\mathbf{d})$ and $k=k(\mathbf{d})$.
23.4 Theorem. Let $(X, L)$ be a general pair, where $X=H_{1} \cap \ldots \cap H_{r}$ is the complete intersection of hypersurfaces $H_{i}$ in $\mathbb{P}^{n}$ of degree $d_{i}$ respectively, $L$ is a linear space of dimension $k$ contained in $X$ which is smooth along $L$ and irreducible. Then if $n \geq n(\mathbf{d})$ and $k=k(\mathbf{d}), X$ is unirational.
Proof. We prove this result by induction on the positive integers $r, d_{1}, \ldots, d_{r}$ and we require the following more precise statement.

Let the notation be as in (23.1). For each $z=(\mathbf{F}, L)$ in $Z$, let $H_{i}(z)$ be the hypersurface in $\mathbb{P}^{n}$ defined by $F_{i}$ and $X_{z}$ be the intersection of these hypersurfaces. Let $U(n, \mathbf{d})$ be the open subset of $Z$ consisting of points $z=$ $(\mathbf{F}, L)$ satisfying the following conditions
(23.4.1) $X_{z}$ is irreducible and the complete intersection of the $H_{i}(z)$.
(23.4.2) $X_{z}$ is smooth along $L$.
(23.4.3) $\phi_{z}$ is surjective.
23.5 Theorem. If $n \geq n(\mathbf{d})$ and $k=k(\mathbf{d})$, then for each $z \in U(n, \mathbf{d}), X_{z}$ is unirational.

Since we have shown that $Z \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(V)$ is dominant, this implies (23.4).

Proof. We proceed by induction on the positive integers $r, d_{1}, \ldots, d_{r}$.
(23.5.1) $r=1$ and $d_{1}=1$.

In this case $X_{z}$ is a linear space and hence it is rational.
(23.5.2) $r>1$ and $d_{i}=1$ for some $i$.

Let $V^{\prime}=V /\left\langle F_{i}\right\rangle$ so that $H_{i}(z)=\mathbb{P}\left(V^{\prime}\right) \subset \mathbb{P}(V)=\mathbb{P}^{n}$. Then $F_{i} \in S_{L}$ gives the $i$-th projection of

$$
\phi_{z}: S_{L}^{*} \rightarrow \oplus_{j=1}^{r} \operatorname{Sym}^{d_{j}-1}\left(Q_{L}\right)
$$

Since $\phi_{z}$ is a surjection, we have an induced surjection

$$
\phi^{\prime}:\left(S_{L} /<F_{i}>\right)^{*} \rightarrow \oplus_{j \neq i} \operatorname{Sym}^{d_{j}-1}\left(Q_{L}\right)
$$

Let $G^{\prime} \subset G$ be the sub-Grassmannian of $k$-dimensional linear subspaces of $H_{i}(z)$ and $Z^{\prime} \subset \oplus_{j \neq i} \operatorname{Sym}^{d_{i}}\left(V^{\prime}\right) \times G^{\prime}$ be the locus of pairs $\left(\mathbf{F}^{\prime}, L\right)$, where $F_{j}^{\prime}$ vanish along $L$. Then, if we take

$$
\mathbf{F}^{\prime}=\left(\left.F_{1}\right|_{H_{i}(z)}, \ldots,\left.F_{i-1}\right|_{H_{i}(z)},\left.F_{i+1}\right|_{H_{i}(z)}, \ldots,\left.F_{r}\right|_{H_{i}(z)}\right)
$$

and $z^{\prime}=\left(\mathbf{F}^{\prime}, L\right)$. Then $z^{\prime}$ lies in $Z^{\prime}$. Note that $\operatorname{dim} V^{\prime}=n-1 \geq n(\mathbf{d})-1=$ $n\left(\mathbf{d}^{\prime}\right)$ and $k=k(\mathbf{d})=k\left(\mathbf{d}^{\prime}\right)$ and $X_{z^{\prime}}=X_{z}$. Further, $\phi_{z^{\prime}}=\phi^{\prime}$ is a surjection so that we have the result by induction in this case.
(23.5.3) $d_{i}>1$ for all $i$.

Choose a splitting of the sequence

$$
0 \rightarrow S_{L} \rightarrow V \rightarrow Q_{L} \rightarrow 0
$$

Then if $P=\mathbb{P}\left(S_{L}\right)$, the blow up $\widetilde{\mathbb{P}(V)_{L}}$ of $\mathbb{P}(V)=\mathbb{P}^{n}$ along $L=\mathbb{P}\left(Q_{L}\right)$ is alternatively described by

$$
\widetilde{\mathbb{P}(V)_{L}}=\mathbb{P}_{P}\left(Q_{L} \times P \oplus \mathcal{O}_{P}(1)\right)
$$

The surjection (induced by the splitting chosen above) $V \times P \rightarrow Q_{L} \times$ $P \oplus \mathcal{O}_{P}(1)$ gives an inclusion $\widetilde{\mathbb{P}(V)_{L}} \subset \mathbb{P}^{n} \times P$. Further, the element $F_{i} \in$ $\operatorname{Sym}^{d_{i}}(V)$ goes to the kernel of

$$
\operatorname{Sym}^{d_{i}}\left(Q_{L} \times P \oplus \mathcal{O}_{P}(1)\right) \rightarrow \operatorname{Sym}^{d_{i}}\left(Q_{L}\right) \times P
$$

which is $\operatorname{Sym}^{d_{i}-1}\left(Q_{L} \times P \oplus \mathcal{O}_{P}(1)\right) \otimes \mathcal{O}_{P}(1)$. Denote these images by $\tilde{F}_{i}$.
The subvariety defined by the vanishing of all the $\tilde{F}_{i}$ is the birational transform of $X$ in $\widehat{\mathbb{P}(V)_{L}}$; this strict transform is just the blow up $\tilde{X_{L}}$ of $X$ along $L$. Since $X$ is smooth along $L$, this is an irreducible variety and the exceptional locus, which is its intersection with $\mathbb{P}\left(Q_{L}\right) \times P$, is also smooth. In particular, the generic fibre of $\tilde{X}_{L} \rightarrow P$ is irreducible and smooth along its intersection with $\mathbb{P}\left(Q_{L}\right)$. Further, this fibre is a complete intersection defined by the simultaneous vanishing of the equations $\tilde{F}_{i}$ which are of degree $d_{i}-1$.

Since $k=k(\mathbf{d})=n(\mathbf{d}-\mathbf{1})$, we can repeat the constructions of section 2 with $V_{1}^{\prime}=Q_{L}$ and $G_{1}^{\prime}$ the Grassmannian of $h=k(\mathbf{d}-\mathbf{1})$ dimensional linear subspaces of $\mathbb{P}\left(V_{1}^{\prime}\right)=L$. Let $Z_{1}^{\prime} \subset \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(V_{1}^{\prime}\right) \times G_{1}^{\prime}$ denote the corresponding incidence locus and

$$
0 \rightarrow S_{1} \rightarrow V_{1}^{\prime} \times G_{1}^{\prime} \rightarrow Q_{1} \rightarrow 0
$$

be the universal sequence on $G_{1}^{\prime}$.
We have a surjection $\phi_{z}: S_{L}^{*} \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(V_{1}^{\prime}\right)$, so that we can form the base change

$$
Z_{1}^{\prime \prime}=Z_{1}^{\prime} \times_{\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(V_{1}^{\prime}\right)} S_{L}^{*}
$$

Then $Z_{1}^{\prime \prime}$ is a vector bundle over the Grassmannian $G_{1}^{\prime}$ and a rational variety. Let $z_{1}^{\prime}: \operatorname{Spec} K \rightarrow Z_{1}^{\prime \prime}$ denote its generic point. From the lemma we deduce
that Spec $K \rightarrow S_{L}^{*}$ is dominant. Since the natural map $S_{L}^{*}-\{0\} \rightarrow \mathbb{P}\left(S_{L}\right)$ is surjective we see that the map $\operatorname{Spec} K \rightarrow \mathbb{P}\left(S_{L}\right)$ is also dominant. Let $Y$ be the pullback of $\tilde{X}_{L} \rightarrow \mathbb{P}\left(S_{L}\right)$ to Spec $K$. Then $Y$ is a complete intersection variety in $\mathbb{P}\left(Q_{L} \otimes K \oplus K\right)$ which is defined by the equations $\tilde{F}_{1}, \ldots, \tilde{F}_{r}$ which are of degrees $d_{1}-1, \ldots, d_{r}-1$ respectively. Further, if $L_{1} \in G_{1}^{\prime}(K)$ is the image of $z_{1}^{\prime}$, then

$$
L_{1} \subset \mathbb{P}\left(Q_{L} \otimes K\right) \subset \mathbb{P}\left(Q_{L} \otimes K \oplus K\right) \subset Y
$$

Further, $Y$ is smooth along its intersection with $\mathbb{P}\left(Q_{L} \otimes K\right)$ hence in particular along $L_{1}$.

By the genericity of $z_{1}^{\prime}$, the induced morphism

$$
\phi_{z_{1}^{\prime}}: S_{1, L_{1}}^{*} \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(Q_{1, L_{1}}\right)
$$

is surjective. But now, if $G_{1}$ is the Grassmannian of $h$-dimensional subspaces of $\mathbb{P}\left(V_{\tilde{1}}^{\prime} \otimes K \oplus K\right)$ and $Z_{1} \subset \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(V_{1}^{\prime} \otimes K \oplus K\right) \times G_{1}$ is as before, let $z_{1}=\left(\tilde{\mathbf{F}}, L_{1}\right) \in Z_{1}$. Then the map for $z_{1}$ is

$$
\phi_{z_{1}}: S_{1, L_{1}}^{*} \oplus K \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}\left(Q_{1, L_{1}}\right)
$$

which restricts to $\phi_{z_{1}^{\prime}}$ and hence is also surjective.
By the induction hypothesis, $Y=X_{z_{1}}$ is unirational over the field $K$. But $K$ is the function field of a rational variety and since Spec $K \rightarrow \mathbb{P}\left(S_{L}\right)$ is dominant $Y \rightarrow X$ is dominant. Thus $X$ is unirational.
23.6 Proof of (23.2.3). The result is trivial in the case (23.2.1), so we only need to show the surjectivity of $\psi_{z}$ for a suitable choice of $z$ in the case (23.2.2). Since the map $F^{1}\left(\operatorname{Sym}^{d_{i}}(V) \times G\right) \rightarrow S \otimes \operatorname{Sym}^{d_{i}-1}(Q)$ is surjective this follows from the following proposition; taking $Q$ to be $Q_{L}$ and $U$ to be $S_{L}^{*}$, the map $\psi$ can be thought of as an element of $S_{L} \otimes \oplus_{i=1}^{r} \operatorname{Sym} d_{i}-1\left(Q_{L}\right)$ which can be lifted to a point $z \in Z$, hence $\psi_{z}=\psi$.
23.6.1 Proposition. Let $n, k$ and $\mathbf{d}=\left(d_{1}, \ldots, d_{r}\right)$ be chosen satisfying (23.2.2). Let $Q$ be a vector space of dimension $k+1$. For any space $U$ of dimension $n-k$ and there exists a map $\psi: U \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q)$ such that the induced map

$$
U \otimes Q \xrightarrow{\psi \otimes \mathrm{Id}} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q) \otimes Q \xrightarrow{\text { product }} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q)
$$

is surjective.
Proof. Since the product homomorphism $\pi: \operatorname{Sym}^{d_{i}-1}(Q) \otimes Q \rightarrow \operatorname{Sym}^{d_{i}}(Q)$ is surjective, we may assume that $u=n-k<\operatorname{dim} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q)$. Let $X$ be
the Grassmannian of $(n-k)$-dimensional linear subspaces of $\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q)$ and $U \subset \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q) \otimes \mathcal{O}_{X}$ be the universal subbundle. The composite homomorphism

$$
U \otimes Q \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q) \otimes Q \otimes \mathcal{O}_{X} \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q) \otimes \mathcal{O}_{X}
$$

is not surjective at some point of $X$ if and only if there is a one dimensional quotient of $\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q)$ where the image of the composite goes to zero.

Let $Y=\mathbb{P}\left(\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q)\right)$; we have a surjection

$$
\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q) \otimes \mathcal{O}_{Y} \rightarrow \mathcal{O}_{Y}(1)
$$

and thus a composite homomorphism

$$
U \otimes Q \otimes \mathcal{O}_{Y} \rightarrow \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q) \otimes Q \otimes \mathcal{O}_{X \times Y} \rightarrow \mathcal{O}_{X} \otimes \mathcal{O}_{Y}(1)
$$

This composite is zero at all the "bad" pairs $(x, y) \in X \times Y$.
Let $\mathcal{F}$ be the cokernel of the natural homomorphism on $Y$

$$
Q \otimes \mathcal{O}_{Y} \rightarrow\left(\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q)\right)^{*} \otimes \mathcal{O}_{Y}(1)
$$

The locus of "bad" pairs, $Z \subset X \times Y$ is then the Grassmanian of rank $u$ quotients of $\mathcal{F}$. We need to show that $Z \rightarrow X$ is not surjective.

Let $Y=\amalg Y_{m}$ be the flattening stratification for $\mathcal{F}$. We have an exact sequence of vector bundles on $Y_{m}$

$$
\left.0 \rightarrow E_{m} \rightarrow Q \otimes \mathcal{O}_{Y_{m}} \rightarrow\left(\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q)\right)^{*} \otimes \mathcal{O}_{Y_{m}}(1) \rightarrow \mathcal{F}\right|_{Y_{m}} \rightarrow 0
$$

where $E_{m}$ has rank $m$. Thus for all $y \in Y_{m}$, the one dimensional quotient of $\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q)$ is zero on $\left(E_{m}\right)_{y} \cdot \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}-1}(Q)$. Thus it is induced from a one dimensional quotient of $\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}\left(Q /\left(E_{m}\right)_{y}\right)$.

Let $A_{m}$ be the Grassmanian of $m$-dimensional subspaces of $Q$ and let $E_{m} \hookrightarrow Q \otimes \mathcal{O}_{A_{m}}$ be the universal subbundle. Let $B_{m}$ be the projective bundle $\mathbb{P}_{A_{m}}\left(\oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}\left(Q \otimes \mathcal{O}_{A_{m}} / E_{m}\right)\right)$. We have a natural morphism $B_{m} \rightarrow Y$ whose image contains $Y_{m}$ as seen above. Thus, we can bound the dimension of $Y_{m}$ and thus also $\left.Z\right|_{Y_{m}}$.

$$
\left.\operatorname{dim} Z\right|_{Y_{m}} \leq \operatorname{dim} B_{m}+u\left(\left.\operatorname{dim} \mathcal{F}\right|_{Y_{m}}-u\right)
$$

Comparing with $\operatorname{dim} X=u\left(\operatorname{dim} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q)-u\right)$ we see that we would be done if
$\left(*_{m}\right) \quad \operatorname{dim} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}\left(Q / E_{m}\right) \leq(u-m)(\operatorname{dim} Q-m)$
Since the conditions of the proposition give us

$$
\begin{equation*}
\operatorname{dim} \oplus_{i=1}^{r} \operatorname{Sym}^{d_{i}}(Q) \leq u \cdot \operatorname{dim} Q \tag{0}
\end{equation*}
$$

we have to show that $\left(*_{m}\right)$ implies $\left(*_{m+1}\right)$. But then, replacing $Q$ by $Q / E_{m}$ we need only show that ( $*_{0}$ ) implies ( $*_{1}$ ). This is easily checked by calculation.

# L'Herméneutique formelle <br> L'infini, le continu, l'espace 

par J.-M. Salanskis

L'herméneutique formelle ou la pensée de la mathématique. Déjà le legs esthétique de Kant permet de considérer l'infini, le continu et l'espace dans une situation herméneutique et le développement de la mathématique moderne confirme largement cet enseignement.
