# AN INVERSION FORMULA FOR WEIGHTED ORBITAL INTEGRALS 

Rebecca A. Herb*

## §1. Introduction

Let $G$ be a reductive Lie group satisfying Harish-Chandra's basic assumptions. Let $A$ be the split component of a parabolic subgroup of $G$ and $T$ a Cartan subgroup of $G$ with $A \subseteq T$. Write $T=T_{I} T_{R}$ where $T_{I}$ is compact and $T_{R}$ is split. Then for $h \in T^{\prime}$, the set of regular elements of $T$, and $f \in C_{c}^{\infty}(G)$, Arthur defines in [1c] a weighted integral of $f$ over the orbit of $h$ by

$$
\begin{equation*}
r_{f}^{A}(h)=\int_{T_{R} \backslash G} f\left(x^{-1} h x\right) v_{A}(x) d \dot{x} \tag{1.1}
\end{equation*}
$$

where $v_{A}$ is a certain weight function corresponding to $A$ defined on $C_{G}(A) \backslash G$ and $d \dot{x}$ is a $G$-invariant measure on the quotient. When $A$ $=\{1\}, r_{f}^{\{1\}}(h)$ is the ordinary orbital integral.

Arthur proves that the distributions $r^{A}(h): f \rightarrow r_{f}^{A}(h), f \in C_{c}^{\infty}(G)$, are tempered, that is, extend continuously to $f \in \mathscr{C}(G)$, the Schwartz space of $G$, and have many properties analogous to those of ordinary orbital integrals. Such weighted orbital integrals occur in the Selberg trace formula for the case of non-compact quotient, and thus it is important to compute their Fourier transforms as tempered distributions [see $1 \mathrm{a}, \mathrm{d}, 5]$.

In the case that $f$ is a matrix coefficient for a discrete series representation of class $\omega$ and with character $\theta_{\omega}$, Arthur proves that

$$
\begin{equation*}
r_{f}^{A}(h)=\varepsilon(T, A)(-1)^{p}\left\langle\theta_{\omega}, f\right\rangle \theta_{\omega}(h) \tag{1.2}
\end{equation*}
$$

[^0]where $p$ is the dimension of $A$ and $\varepsilon(T, A)$ is 1 if $A=T_{R}$ and is 0 otherwise. This gives the Fourier inversion formula for $r^{A}(h)$ restricted to the space ${ }^{\circ} \mathscr{C}_{C}(G)$ of cusp forms on $G$. It also shows that the weighted orbital integrals, like ordinary orbital integrals, have important connections with the harmonic analysis on $G$.

In the case that $A=\{1\}$, (1.2) is a well-known theorem of HarishChandra. In order to motivate the results of this paper, it is useful to review other results of Harish-Chandra on orbital integrals. Thus let $P$ $=M A_{1} N$ be a cuspidal parabolic subgroup of $G$. For $\omega$ an equivalence class of discrete series representations of $M$ and $v \in \mathscr{F}$, the real dual of the Lie algebra of $A_{1}$, let $\theta_{\omega, v}$ be the corresponding unitary character induced from $P$. Let $W(\omega)=\left\{s \in N_{G}\left(A_{1}\right) / C_{G}\left(A_{1}\right), \quad s \omega=\omega\right\}$. For $\alpha \in C_{c}^{\infty}(\mathscr{F})$, let $f=\varphi_{\alpha}$ be a wave packet corresponding to $\omega$. Then Harish-Chandra proves that if $h \in T^{\prime}$ where $T$ is a Cartan subgroup of $G$ with $\operatorname{dim} T_{R} \geq \operatorname{dim} A_{1}$, then

$$
\begin{equation*}
r_{f}(h)=\varepsilon\left(T, A_{1}\right)[W(\omega)]^{-1} \int_{\mathscr{F}}\left\langle\theta_{\omega, v}, f\right\rangle \theta_{\omega, v}(h) d v . \tag{1.3}
\end{equation*}
$$

Here $\varepsilon\left(T, A_{1}\right)$ is 1 if $\operatorname{dim} T_{R}=\operatorname{dim} A_{1}$ and is 0 otherwise [2c].
Let $\mathscr{C}_{A_{1}}(G)$ denote the subspace of $\mathscr{C}(G)$ spanned by wave packets coming from some parabolic $P$ with split component $A_{1}$. Then we see from (1.3) that for $f \in \mathscr{C}_{A_{1}}(G)$ and $h \in T^{\prime}$, if $\operatorname{dim} A_{1}<\operatorname{dim} T_{R}, r_{f}(h)=0$, while if $\operatorname{dim} T_{R}=\operatorname{dim} A_{1}, r_{f}(h)$ is possibly non-zero but still is given by a simple formula. When $\operatorname{dim} A_{1}>\operatorname{dim} T_{R}$, the formula for $r_{f}(h)$ becomes much more complicated (see [3b]).

Returning to the case of weighted orbital integrals, if $A=T_{R}$, then the distribution $r^{A}(h), h \in T^{\prime}$, is non-trivial on the space of cusp forms. Thus in this case we expect that for $f \in \mathscr{C}_{A_{1}}(G), \operatorname{dim} A_{1}>0$, the Fourier inversion formula for $r_{f}^{A}(h)$ will be complicated. However, if $A \subsetneq T_{R}$, so that $r_{f}^{A}(h)=0$ for all $f \in^{\circ} \mathscr{C}(G)$, it is reasonable to expect that $r_{f}^{A}(h), f \in \mathscr{C}_{A_{1}}(G)$, may be given by a relatively simple formula for $A_{1}$ of sufficiently small dimension. This is indeed the case.

Thus let $P=M A_{1} N$ be a cuspidal parabolic subgroup of $G$ with $\operatorname{dim} A_{1} \leq \operatorname{dim} T_{R}-\operatorname{dim} A$. Let $\omega$ be an equivalence class of discrete series representations of $M$. For $\alpha \in C_{c}^{\infty}(\mathscr{F})$, let $f=\varphi_{\alpha}$ be a wave packet corresponding to $\omega$. We will define a "weighted character" $\theta_{\omega, v}^{A}$ on $T^{\prime}$ so that

$$
\begin{equation*}
r_{f}^{A}(h)=\varepsilon\left(T, A, A_{1}\right)(-1)^{p}[W(\omega)]^{-1} \int_{\mathscr{F}}\left\langle\theta_{\omega, v}, f\right\rangle \theta_{\omega, v}^{A}(h) d v \tag{1.4}
\end{equation*}
$$

where $\varepsilon\left(T, A, A_{1}\right)$ is 1 if $\operatorname{dim} T_{R}=\operatorname{dim} A+\operatorname{dim} A_{1}$ and is 0 otherwise.

Note that (1.4) shows that restricted to $\mathscr{C}_{A_{1}}(G), \operatorname{dim} A_{1} \leq \operatorname{dim} T_{R}$ $-\operatorname{dim} A, r^{A}(h)$ is invariant as a distribution. However, $r^{A}(h)$ is not an invariant distribution on $\mathscr{C}(G)$. Thus when $f \in \mathscr{C}_{A_{1}}(G), \operatorname{dim} A_{1}>\operatorname{dim} T_{R}$ $-\operatorname{dim} A$, we can expect the problem of computing $r_{f}^{A}(h)$ to become much more difficult.

In section §2 we review the basic definitions and results of Arthur on weighted orbital integrals and of Harish-Chandra on wave packets which will be needed to prove (1.4). In section §3 we define the "weighted characters" $\theta_{\omega, v}^{A}$ which appear in (1.4) and show that they retain many of the basic properties of the ordinary characters $\theta_{\omega, v}$. In section $\S 4$ we study distribution-valued functions on $T^{\prime}$ of the type that occur in (1.4), and in $\S 5$ we give the proof of (1.4).

## §2. Background material

Let $G$ be a reductive Lie group with Lie algebra $\mathfrak{g}$. Let $K$ be a maximal compact subgroup of $G$ and $\theta$ the corresponding Cartan involution. Let $B$ be a real symmetric bilinear form on g . We will assume that ( $G, K, \theta, B$ ) satisfy the general assumptions of Harish-Chandra in [2b] and that Haar measures are normalized as in [2b].

Subgroups of $G$ will be denoted by capital letters and the associated subalgebras by the corresponding lower case German letters. The complexification of any Lie subalgebra $\mathfrak{h}$ of $\mathfrak{g}$ will be denoted $\mathfrak{h}$. All Cartan subgroups $T$ of $G$ will be assumed to be $\theta$-stable. We will write $T^{\prime}$ for the set of regular elements of $T$ and decompose $T=T_{I} T_{R}$ where $T_{I}$ $=T \cap K$ and $T_{R}$ is a vector subgroup of $T$ with Lie algebra $\mathrm{t}_{R}$ contained in the -1 eigenspace for $\theta$. We will write $N_{G}(T)$ for the normalizer of $T$ in $G, T_{0}$ for the center of $T$, and $W(G, T)$ for $N_{G}(T) / T_{0} . \Phi=\Phi\left(\mathrm{g}_{\mathbf{c}}, \mathrm{t}_{\mathbf{c}}\right)$ will denote the set of roots of $g_{\mathbf{c}}$ with respect to $\mathrm{t}_{\mathbf{c}}, \Phi_{R}$ and $\Phi_{I}$ the subsets of $\Phi$ taking real and pure imaginary values on $t$ respectively. $\Phi_{C}$ denotes the complement in $\Phi$ of $\Phi_{R} \cup \Phi_{I}$. For each $\gamma \in \Phi_{C}$ there is $\gamma^{\sigma} \in \Phi_{C}$ such that for all $H \in \mathrm{t}, \gamma^{\sigma}(H)=\overline{\gamma(H)}$. The real dual of t will be denoted by $\mathrm{t}^{*}$, the complex dual by $\mathbf{t}_{\mathbf{c}}^{*}$. We will identify elements of $\mathrm{t}_{\mathbf{c}}$ and $\mathrm{t}_{\mathbf{c}}^{*}$ via the bilinear form $B . W=W\left(g_{\mathbf{c}}, \mathrm{t}_{\mathbf{c}}\right)$ denotes the Weyl group corresponding to $\Phi$. For any $\beta \in \Phi, s_{\beta} \in W$ denotes the reflection corresponding to $\beta$ and $\xi_{\beta}$ the character of $T$ corresponding to $\beta$.

For the convenience of the reader we will review some definitions and lemmas of Arthur. The reader is referred to [1c] for details. Let $A$ be a special vector subgroup of $G$, that is a split component of a parabolic subgroup of $G$ as defined in $[1 \mathrm{c}, \S 1]$ and $\mathscr{Y}$ an $A$-orthogonal set. Corresponding to $\mathscr{Y}$, Arthur defines a weight function $v(x: \mathscr{Y}), x \in G$, which is
left-invariant by $C_{G}(A)$, the centralizer in $G$ of $A$. Let $\mathscr{G}$ denote the universal envelopping algebra of $\mathfrak{g}_{\mathbf{c}}$, and for any $X \in \mathscr{G}$, let $c_{0}(X)$ denote the constant term of $X$. Let $\mathscr{G}_{A}$ be the set of elements in $\mathscr{G}$ invariant under the adjoint action of $A$. For $X \in \mathscr{G}_{A}$ we will write $D_{X}$ for the rightinvariant differential operator associated to $X$.

Let $T$ be a Cartan subgroup of $G$ with $A \subseteq T$. Then for all $h \in T^{\prime}$, $f \in C_{c}^{\infty}(G)$, and $X \in \mathscr{G}_{A}$, Arthur defines

$$
\begin{equation*}
\langle r(h: \mathscr{Y}: X), f\rangle=\int_{T_{R} \backslash \mathbf{G}} f\left(x^{-1} h x\right) D_{X} v(x: \mathscr{Y}) d \dot{x} \tag{2.1}
\end{equation*}
$$

where $d \dot{x}$ is a $G$-invariant measure on the quotient.
Let $\mathfrak{z}$ denote the centralizer of $\mathrm{t}_{R}$ in $\mathfrak{g}$ and $Z(t)$ the centralizer of $\mathfrak{z}$ in $K$. Let $\Phi_{I}^{+}$be a set of positive roots for $(3, t)$. Let:

$$
\begin{aligned}
& \Delta_{+}(h)=\left|\operatorname{det}\left(1-A d\left(h^{-1}\right)\right)_{\mathbf{g} / 3}\right|^{1 / 2}, \quad h \in T ; \\
& \Delta_{I}(H)=\prod_{\beta \in \Phi_{I}^{+}}\left(e^{\beta(H) / 2}-e^{-\beta(H) / 2}\right), \quad H \in \mathrm{t} ; \\
& \tilde{\Delta}(\zeta, H)=\Delta_{I}(H) \Delta_{+}(\zeta \exp H), \quad \zeta \in Z(\mathrm{t}), H \in \mathrm{t} .
\end{aligned}
$$

For $\zeta \in Z(\mathrm{t}), H \in \mathrm{t}^{\prime}(\zeta)=\left\{H \in \mathrm{t}: \zeta \exp H \in T^{\prime}\right\}$, and $f \in C_{c}^{\infty}(G)$, define

$$
\begin{align*}
& R_{f}^{T, A}(\zeta, H: \mathscr{Y}: X)=\langle R(\zeta, H: \mathscr{Y}: X), f\rangle= \\
&=\tilde{\Delta}(\zeta, H)\langle r(\zeta \exp H: \mathscr{Y}: X), f\rangle \tag{2.2}
\end{align*}
$$

Lemma 2.3 (Arthur): Let $\zeta \in Z(\mathrm{t})$. For each $H \in \mathrm{t}^{\prime}(\zeta)$ the distribution $R(\zeta, H: \mathscr{Y}: X)$ is tempered. For every $f \in \mathscr{C}(G)$, the function $R_{f}(\zeta, H: \mathscr{Y}: X)$ is infinitely differentiable for $H \in \mathbf{t}^{\prime}(\zeta)$.

Let $\mathscr{Z}$ denote the center of $\mathscr{G}, S\left(\mathrm{t}_{\mathbf{c}}\right)$ the symmetric algebra on $\mathrm{t}_{\mathbf{c}}, I\left(\mathrm{t}_{\mathbf{c}}\right)$ the set of Weyl group invariants in $S\left(\mathrm{t}_{\mathbf{c}}\right)$, and $\gamma=\gamma_{\mathrm{g} / \mathrm{t}}$ the HarishChandra isomorphism from $\mathscr{Z}$ onto $I\left(\mathrm{t}_{\mathbf{c}}\right)$. Arthur defines ideals $\mathscr{G}_{A}(0) \subseteq \mathscr{G}_{A}(1) \subseteq \ldots$ of $\mathscr{G}_{A}$ so that $\bigcup_{r \geq 0} \mathscr{G}_{A}(r)=\mathscr{G}_{A}, \mathscr{G}_{A}(r) \mathscr{G}_{A}\left(r^{\prime}\right) \subseteq \mathscr{G}_{A}(r$ $\left.+r^{\prime}\right), r, r^{\prime} \geq 0, D_{X} v(x: \mathscr{Y})=0$ if $X \in \mathscr{G}_{A}(p+1), p=\operatorname{dim} A$, and $c_{0}(X)=0$ if $X \in \mathscr{G}_{A}(1)$.

Lemma 2.4 (Arthur): For any $z \in \mathscr{Z}$ there are elements $\left\{X_{i}: 1 \leq i \leq r\right\}$ in $\mathscr{G}_{A}(1)$ and differential operators $\left\{\partial_{i}: 1 \leq i \leq r\right\}$ on $\mathrm{t}^{\prime}(\zeta)$ so that for every $\zeta \in Z(\mathrm{t}), H \in \mathrm{t}^{\prime}(\zeta), X \in \mathscr{G}_{A}$, and $f \in \mathscr{C}(G)$,

$$
R_{z f}(\zeta, H: \mathscr{Y}: X)-R_{f}\left(\zeta, H_{i} ; \partial \gamma(z): \mathscr{Y}: X\right)=\sum_{i=1}^{r} R_{f}\left(\zeta, H ; \partial_{i}: \mathscr{Y}: X X_{i}\right) .
$$

Fix $\zeta \in Z(\mathrm{t})$ and $\beta \in \Phi_{R}(\zeta)=\left\{\beta \in \Phi_{R}: \xi_{\beta}(\zeta)=1\right\}$. Let $\mathfrak{t}_{\beta}^{0}=\{H \in \mathrm{t}: \beta(H)$ $=0\}, \mathfrak{a}_{\beta}=\mathfrak{a} \cap \mathrm{t}_{\beta}^{0}$, and $A_{\beta}=\exp \left(\mathfrak{a}_{\beta}\right)$. Let $H_{\beta}^{\prime} \in \mathrm{t}$ be dual to $2 \beta /\langle\beta, \beta\rangle$ and let $X_{\beta}^{\prime}$ and $Y_{\beta}^{\prime} \in \mathfrak{g}$ be root vectors for $\beta$ satisfying $\left[X_{\beta}^{\prime}, Y_{\beta}^{\prime}\right]=H_{\beta}^{\prime}, Y_{\beta}^{\prime}=$ $-\theta X_{\beta}^{\prime}$. Then $\mathrm{t}_{\beta}=\mathrm{t}_{\beta}^{0}+\mathbf{R}\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right)$ is a Cartan subalgebra of g and we denote the corresponding Cartan subgroup by $T_{\beta}$. Let $\Lambda=\exp ($ $\left.-\pi i / 4 \operatorname{ad}\left(X_{\beta}^{\prime}+Y_{\beta}^{\prime}\right)\right)$ be the associated Cayley transform. Let $n_{\beta}(A)$ denote the cosine of the angle in $\mathrm{t}_{R}$ between $\beta$ and $\mathfrak{a}$. If $H \in \mathrm{t}^{\prime}(\zeta)$, set $\tau_{\beta}(H)=n_{\beta}(A)\left\|H_{\beta}^{\prime}\right\| \log \left|e^{\beta(H) / 2}-e^{-\beta(H) / 2}\right|$, and define

$$
\begin{equation*}
S_{f}^{\beta}(\zeta, H: \mathscr{Y}: X)=R_{f}(\zeta, H: \mathscr{Y}: X)+\tau_{\beta}(H) R_{f}^{T, A_{\beta}\left(\zeta, H: \mathscr{Y}_{\beta}: X\right)} \tag{2.5}
\end{equation*}
$$

where $\mathscr{Y}_{\beta}$ is an $A_{\beta}$-orthogonal set depending on $\mathscr{Y}$. Let $\mathfrak{t}_{\beta}^{0}(\zeta)=\left\{H \in \mathfrak{t}_{\beta}^{0}\right.$ $: \xi_{\alpha}(\zeta \exp H) \neq 1$ for any $\left.\alpha \in \Phi, \alpha \neq \pm \beta\right\}$. For $H_{0} \in \mathrm{t}_{\beta}^{0}(\zeta)$, write $S\left(H_{0}\right)^{ \pm}$ $=\lim _{t \rightarrow 0^{ \pm}} S\left(H_{0}+t H_{\beta}^{\prime}\right)$.

Lemma 2.6 (Arthur): Let $u \in S\left(\mathrm{t}_{\mathbf{c}}\right), \quad f \in \mathscr{C}(G)$. Then for $H_{0} \in \mathrm{t}_{\beta}^{0}(\zeta)$, $S_{f}^{\beta}\left(\zeta, H_{0} ; \partial u: \mathscr{Y}: X\right)^{+}-S_{f}^{\beta}\left(\zeta, H_{0} ; \partial u: \mathscr{Y}: X\right)^{-}=n_{\beta}(A) \lim _{\theta \rightarrow 0} R_{f}^{T_{\beta}, A_{\beta}}\left(\zeta, H_{0}+\right.$ $\left.+\theta\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right) ; \partial \Lambda\left(s_{\beta} u-u\right): \mathscr{Y}_{\beta}: X\right)$ where the limits all exist uniformly for $H_{0}$ in compacta of $\mathrm{t}_{\beta}^{0}(\zeta)$.

Lemma 2.7 (Arthur): Let $u \in S\left(\mathrm{t}_{\mathbf{c}}\right), f \in \mathscr{C}(G)$. Then for $H_{0} \in \mathrm{t}_{\beta}^{0}(\zeta)$,

$$
\begin{aligned}
& \lim _{\theta \rightarrow 0^{+}} R_{f}^{T_{\beta}, A_{\beta}}\left(\zeta, H_{0}+\theta\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right) ; \partial \Lambda u: \mathscr{Y}_{\beta}: X\right)- \\
& \lim _{\theta \rightarrow 0^{-}} R_{f}^{T_{\beta}, A_{\beta}}\left(\zeta, H_{0}+\theta\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right) ; \partial \Lambda u: \mathscr{Y}_{\beta}: X\right)= \\
& -\pi i\left\|H_{\beta}^{\prime}\right\| \lim _{t \rightarrow 0} R_{f}^{T, A_{\beta}}\left(\zeta, H_{0}+t H_{\beta}^{\prime} ; \partial u: \mathscr{Y}_{\beta}: X\right)
\end{aligned}
$$

where the limits all exist uniformly for $H_{0}$ in compacta of $\mathrm{t}_{\beta}^{0}(\zeta)$.
Lemma 2.7 gives boundary conditions for $R_{f}$ across any hyperplane determined by a singular imaginary root. It follows easily from the proof of 2.6 (Theorem 6.1 of [1c]) and facts about ordinary orbital integrals that if $\beta$ is a compact root of $(\mathfrak{g}, \mathrm{t})$ and $H_{0} \in \mathrm{t}$ satisfies $e^{\beta\left(H_{0}\right)}=1$, $\xi_{\alpha}\left(\zeta \exp H_{0}\right) \neq 1$ for any $\alpha \in \Phi, \alpha \neq \pm \beta$, then $R_{f}(\zeta, H: \mathscr{Y}: X)$ extends to a smooth function around $H=H_{0}$.

For $H \in \mathrm{t}^{\prime}(\zeta)$, let $m(H)=\min \left\{\left|1-\xi_{\alpha}(\zeta \exp H)^{-1}\right|: \alpha \in \Phi\right.$ and $\left.\left.\alpha\right|_{a} \neq 0\right\}$. Let $L(\zeta \exp H)=|\log m(H)|$.

Lemma 2.8: Given any $u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$ there is a continuous seminorm $v$ on
$\mathscr{C}(G)$ so that for all $f \in \mathscr{C}(G)$ and $H \in \mathrm{t}^{\prime}(\zeta)$,

$$
\left|R_{f}(\zeta, H ; \partial u: \mathscr{Y}: X)\right| \leq v(f)(1+L(\zeta \exp H))^{p}
$$

Proof: In the case that $u=1$, this result is a special case of Corollary 7.4 of [1c]. For general $u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$ it can be obtained by using the argument of Arthur in Lemma 8.1 of [1c].

We now turn to results of Harish-Chandra on wave packets which can be found in [2c, §20]. Let $P=M A_{1} N$ be a cuspidal parabolic subgroup of $G$. Let $\varepsilon_{2}(M)$ denote the set of equivalence classes of irreducible unitary square-integrable representations of $M$. Let $\mathscr{C}_{\omega}(M)$ denote the closed subspace of $\mathscr{C}(M)$ spanned by $K_{M}$-finite matrix coefficients of $\omega$ where $K_{M}=K \cap M$. For any $v \in \mathscr{F}=\mathfrak{a}_{1}^{*}$, let $\pi_{\omega, v}$ be the tempered unitary representation of $G$ induced from $\omega \otimes e^{i v} \otimes 1$ on $P$. Let $\theta_{\omega, \nu}$ and $\theta_{\omega}$ denote the characters of $\pi_{\omega, v}$ and $\omega$ considered as functions on $G^{\prime}$ and $M^{\prime}$ respectively. For $f \in \mathscr{C}(G)$, write

$$
\left\langle\theta_{\omega, v}, f\right\rangle=\int_{G} f(x) \overline{\theta_{\omega, v}(x)} d x
$$

For $\omega \in \varepsilon_{2}(M), \psi \in \mathscr{C}_{\omega}(M), \alpha \in C_{c}^{\infty}(\mathscr{F})$, and $x \in G$, define

$$
\begin{equation*}
\varphi_{\alpha}(x)=\int_{\mathscr{F}} \alpha(v) E(P: \psi: v: x) \mu(\omega: v) d v \tag{2.9}
\end{equation*}
$$

where $E(P: \psi: v)$ is the Eisenstein integral defined in [2b] and $\mu(\omega: v) d v$ is the Plancherel measure corresponding to $\pi_{\omega, v}, v \in \mathscr{F}$. Then $\varphi_{\alpha} \in \mathscr{C}(G)$ is called a wave packet for $\omega \in \varepsilon_{2}(M)$, and $\alpha \rightarrow \varphi_{\alpha}$ is a continuous mapping from $C_{c}^{\infty}(\mathscr{F})$ into $\mathscr{C}(G)$. Extend $\mathfrak{a}_{1}$ to a Cartan subalgebra $\mathfrak{h}=\mathfrak{h}_{I}+\mathfrak{a}_{1}$ of $\mathfrak{g}$ with $\mathfrak{h}_{I} \subseteq \mathfrak{m}$. Let $\lambda \in i \mathfrak{h}_{I}^{*}$ correspond to the infinitesimal character of $\omega$. For $q \in I\left(\mathfrak{h}_{\mathbf{c}}\right)$, let $p(q)$ be the polynomial function on $\mathscr{F}$ given by $p(q: v)$ $=q(\lambda+i v), v \in \mathscr{F}$. Then if $q \in I\left(\mathfrak{h}_{\mathbf{c}}\right)$ and $z=\gamma_{\mathbf{g} / \mathfrak{h}}^{-1}(q) \in \mathscr{Z}$, then

$$
\begin{equation*}
z \varphi_{\alpha}=\varphi_{p(q) \alpha} \tag{2.10}
\end{equation*}
$$

Finally, for $\omega$ and $\psi$ fixed as above, there is a constant $c$ so that for all $\alpha \in C_{c}^{\infty}(\mathscr{F}), v \in \mathscr{F}$,

$$
\begin{equation*}
\left\langle\theta_{\omega, v}, \varphi_{\alpha}\right\rangle=c \sum_{s \in W(\omega)} \alpha(s v) . \tag{2.11}
\end{equation*}
$$

## §3. Weighted characters

Let $A, B$ be subspaces of a Euclidean vector space with $\operatorname{dim} A$ $=\operatorname{dim} B=m$. Let $\left\{v_{1}, \ldots, v_{m}\right\}$ and $\left\{w_{1}, \ldots, w_{m}\right\}$ be orthonormal bases of $B$ and $A$ respectively. Define $c(B, A)=|\operatorname{det} X|$ where $X$ is the $m \times m$ matrix with entries $x_{i j}=\left\langle v_{i}, w_{j}\right\rangle$. Then $c(B, A)=c(A, B)$ is independent of the choices of orthonormal bases and is equal to the volume of a unit cube in $B$ projected onto $A$.

For any vector $v \neq 0$, let $n_{v}(A)$ be the cosine of the angle between $v$ and $A$ and $A_{v}, B_{v}$ be the subspaces of $A, B$ respectively which are orthogonal to $v$.

Lemma 3.1: If $v \in B, v \neq 0$, then $c(B, A)=n_{v}(A) c\left(B_{v}, A_{v}\right)$.
Proof: Pick an orthonormal basis for $B$ so that $v_{1}=v /\|v\|$. Let $v_{A}$ be the projection of $v$ onto $A$. If $v_{A}=0$, then $n_{v}(A)=0$ and $\left\langle v_{1}, w\right\rangle=0$ for all $w \in A$ so that $c(A, B)=0$. Assume $v_{A} \neq 0$. Choose an orthonormal basis for $A$ with $w_{1}=v_{A} /\left\|v_{A}\right\|$. Then $\left\langle v_{1}, w_{1}\right\rangle=n_{v}(A)$ and $\left\langle v_{1}, w_{j}\right\rangle=0$ for $j \geq 2$. Thus $c(A, B)=n_{v}(A)\left|\operatorname{det} X^{*}\right|$ where $X^{*}=\left(\left\langle v_{i}, w_{j}\right\rangle\right), 2 \leq i$, $j \leq m$ is the matrix corresponding to $A_{v}$ and $B_{v}$.

We will now use the constants $c(B, A)$ to define the weighted characters which appears in (1.4).

Let $P=M A_{1} N$ be a cuspidal parabolic subgroup of $G$. Write $L$ $=M A_{1}$. Let $\omega \in \varepsilon_{2}(M)$ and $v \in \mathscr{F}=\mathfrak{a}_{1}^{*}$. For $T$ a Cartan subgroup of $G$, let $H_{1}, \ldots, H_{k}$ be a complete set of representatives for distinct $L$ conjugacy classes of Cartan subgroups of $L$ for which $H_{i}=x_{i} T x_{i}^{-1}$, $x_{i} \in G, 1 \leq i \leq k$. For $h \in T^{\prime}$, write $h_{i}=x_{i} h x_{i}^{-1} \in H_{i}^{\prime}$. Then

$$
\begin{equation*}
\theta_{\omega, v}(h)=\Delta_{+}^{G}(h)^{-1} \sum_{i=1}^{k} \sum_{w \in W\left(L, H_{i}\right) \backslash W\left(G, H_{i}\right)} \Delta_{+}^{L}\left(w h_{i}\right)\left(\theta_{\omega} \otimes e^{i v}\right)\left(w h_{i}\right) \tag{3.2}
\end{equation*}
$$

where $\Delta_{+}^{G}, \Delta_{+}^{L}$ are the functions $\Delta_{+}$defined on $T$ and $H_{i}, 1 \leq i \leq k$, in §2 when $T$ and $H_{i}$ are considered as Cartan subgroups of $G$ and $L$ respectively. Note that if no conjugate of $T$ lies in $L$, then $\theta_{\omega, v}=0$ on $T^{\prime}$.

Now let $A$ be a special vector subgroup of $G$ with $A \subseteq T_{R}$ and $\operatorname{dim} T_{R}$ $=\operatorname{dim} A+\operatorname{dim} A_{1}$. For $h \in T^{\prime}$ define $x_{1}, \ldots, x_{k}$ and $h_{1}, \ldots, h_{k}$ as above. For $1 \leq i \leq k$ and $w \in W\left(G, H_{i}\right)$, ad $x_{i}^{-1} w^{-1} A_{1} \subseteq T_{R}$ and is independent of the representative of the coset $W\left(L, H_{i}\right) w$ chosen. Define $B_{w}$ to be the orthogonal complement in $T_{R}$ of ad $x_{i}^{-1} w^{-1} A_{1}$. (We consider $T_{R}$ as a Euclidean vector space via the exponential map isomorphism with $\mathrm{t}_{R}$.)

Then $B_{w}$ is a subspace of $T_{R}$ with $\operatorname{dim} B_{w}=\operatorname{dim} A$. Define

$$
\begin{equation*}
\theta_{\omega, v}^{A}(h)=\Delta_{+}^{G}(h)^{-1} \sum_{i=1}^{k} \sum_{w \in W\left(L, H_{i}\right) \backslash W\left(G, H_{i}\right)} c\left(B_{w}, A\right) \Delta_{+}^{L}\left(w h_{i}\right)\left(\theta_{\omega} \otimes e^{i v}\right)\left(w h_{i}\right) . \tag{3.3}
\end{equation*}
$$

Note that $\theta_{\omega, v}^{A}$ is not an invariant function on $G^{\prime}$. It is easy to check from the definition that in fact, if $h \in T^{\prime}$ and $y \in G$, then

$$
\begin{equation*}
\theta_{\omega, v}^{A}(h)=\theta_{\omega, v}^{y A y^{-1}}\left(y h y^{-1}\right) . \tag{3.4}
\end{equation*}
$$

For $\zeta \in Z(\mathrm{t})$ and $H \in \mathrm{t}^{\prime}(\zeta)$, define

$$
\begin{aligned}
& \tilde{\Phi}_{\omega, v}(\zeta, H)=\tilde{\Delta}(\zeta, H) \theta_{\omega, v}(\zeta \exp H) \text { and } \\
& \tilde{\Phi}_{\omega, v}^{A}(\zeta, H)=\tilde{\Delta}(\zeta, H) \theta_{\omega, v}^{A}(\zeta \exp H) .
\end{aligned}
$$

Assume for simplicity that $T \subseteq L$. (Because of (3.4) this leads to no loss of generality.) Let $\mathrm{t}_{M}=\mathrm{t} \cap \mathfrak{m}$ and write $\tilde{\Phi}_{\omega}(\zeta, H)=$ $=\Delta_{I}(H) \Delta_{+}^{L}(\zeta \exp H) \theta_{\omega}(\zeta \exp H)$ for $H \in \mathrm{t}_{M}^{\prime}(\zeta)$. Let $\lambda \in \mathrm{t}_{M, \mathrm{c}}^{*}$ correspond to the infinitesimal character of $\omega$. That is, $\lambda$ is a regular element of $\mathrm{t}_{M, \mathbf{c}}^{*}$ so that $\tilde{\Phi}_{\omega}(\zeta, H ; \partial q)=q(\lambda) \tilde{\Phi}_{\omega}(\zeta, H)$ for all $q \in I\left(\mathrm{t}_{M, \mathbf{c}}\right)$ and $H \in \mathrm{t}_{M}^{\prime}(\zeta)$. Fix $\zeta \in Z(\mathrm{t})$ and let $\Omega(\zeta)=\left\{H \in \mathrm{t}: \beta(H) \neq 0\right.$ for all $\left.\beta \in \Phi_{R}(\zeta)\right\}$.

Lemma 3.5: For any connected component $F$ of $\Omega(\zeta)$ there are constants $c_{s}(F), s \in W=W\left(\mathrm{~g}_{\mathbf{c}}, \mathrm{t}_{\mathbf{c}}\right)$, so that for all $H \in F$,

$$
\tilde{\Phi}_{\omega, v}(\zeta, H)=\sum_{s \in W} c_{s}(F) \exp (s(\lambda+i v)(H))
$$

and

$$
\tilde{\Phi}_{\omega, v}^{A}(\zeta, H)=\sum_{s \in W} c_{s}(F) c\left(B_{s}, A\right) \exp (s(\lambda+i v)(H))
$$

Here $c_{s}(F)=0$ unless $s A_{1} \subseteq T_{R}$, and in this case $B_{s}$ is the orthogonal complement in $T_{R}$ of $s A_{1}$. Further, if $\beta \in \Phi_{R}(\zeta)$ and $F, s_{\beta} F$ are adjacent chambers of $\Omega(\zeta)$, then $c_{s}(F)=c_{s}\left(s_{\beta} F\right)$ unless $\left.\beta\right|_{s \alpha_{1}}=0$.

Proof: Fix $H \in F$ and let $h=\zeta \exp H$. Define $x_{1}, \ldots, x_{k}$ as in (3.2). Let $W_{i}$ be a set of representatives for the cosets $W\left(L, H_{i}\right) \backslash W\left(G, H_{i}\right), 1 \leq i \leq k$. Then using (3.2) and (3.3),

$$
\tilde{\Phi}_{\omega, v}(\zeta, H)=\sum_{i=1}^{k} \sum_{w \in W_{i}} \varepsilon(w)\left(\tilde{\Phi}_{\omega} \otimes e^{i v}\right)\left(w \zeta_{i}, w H_{i}\right)
$$

and

$$
\tilde{\Phi}_{\omega, v}^{A}(\zeta, H)=\sum_{i=1}^{k} \sum_{w \in W_{i}} \varepsilon(w) c\left(B_{w}, A\right)\left(\tilde{\Phi}_{\omega} \otimes e^{i v}\right)\left(w \zeta_{i}, w H_{i}\right)
$$

where $\zeta_{i}=x_{i} \zeta x_{i}^{-1}, H_{i}=\operatorname{ad} x_{i}(H), 1 \leq i \leq k$, and $\varepsilon(w)=\Delta_{I}(H)^{-1} \Delta_{I}\left(w H_{i}\right)$ $= \pm 1$ depends on the choices of positive systems of imaginary roots which have been made, but not on $H$. Fix $1 \leq i \leq k$, and write $\mathfrak{b}$ for the Lie algebra of $H_{i}$. Write $\left.W_{M}=W \mathbf{m}_{\mathbf{c}}, \mathrm{t}_{M, \mathbf{c}}\right)$. Then there is $y \in M_{\mathbf{C}}$ so that Ad $y\left(\mathrm{t}_{\mathbf{c}}\right)=\mathfrak{h}_{\mathbf{c}}$. Using the theory of characters on $M$, for every $w \in W_{i}$ and $\sigma \in W_{M}$ there are uniquely determined constants $c_{\sigma}(i, w)$ depending only on the component of $\mathrm{t}^{\prime}(i, w)=\left\{H \in \mathrm{t}: \beta(H) \neq 0\right.$ for all $\beta \in \Phi_{R}(\zeta)$ such that $\left.\beta \mid \operatorname{Ad} x_{i}^{-1} w^{-1} \mathfrak{a}_{1} \neq 0\right\}$ containing $F$ so that

$$
\left(\tilde{\Phi}_{\omega} \otimes e^{i v}\right)\left(w \zeta_{i}, w H_{i}\right)=\sum_{\sigma \in W_{M}} c_{\sigma}(i, w) \exp (s(i, w) \sigma(\lambda+i v)(H))
$$

where $s(i, w) \in W$ represents the action of $\operatorname{Ad} x_{i}^{-1} w^{-1} \operatorname{Ad} y$ on $\mathrm{t}_{\mathbf{c}}$ and so satisfies $s(i, w) A_{1}=\operatorname{Ad} x_{i}^{-1} w^{-1} A_{1} \subseteq T_{R}$. Note that for all $\sigma \in W_{M}$, $s(i, w) \sigma A_{1}=s(i, w) A_{1}$, so that $B_{w}=B_{s(i, w) \sigma}$ for all $\sigma \in W_{M}$. Further, one can check that any $s \in W$ can be written in at most one way as $s$ $=s(i, w) \sigma, 1 \leq i \leq k, w \in W_{i}, \sigma \in W_{M}$. Thus we can write $\tilde{\Phi}_{\omega, v}$ and $\tilde{\Phi}_{\omega, v}^{A}$ as claimed in the lemma where $c_{s}(F)=0$ if $s$ is not of the form $s=s(i, w) \sigma$ for some $1 \leq i \leq k, w \in W_{i}$, and $\sigma \in W_{M}$, and if $s=s(i, w) \sigma$, then $c_{s}(F)$ $=\varepsilon(w) c_{\sigma}(i, w)$. If $\beta \in \Phi_{R}(\zeta), F, s_{\beta} F$ are adjacent chambers of $\Omega(\zeta)$, and $\left.\beta\right|_{s a_{1}} \neq 0, s=s(i, w) \sigma$, then $F$ and $s_{\beta} F$ lie in the same component of $\mathrm{t}^{\prime}(i, w)$ so that $c_{s}(F)=c_{s}\left(s_{\beta} F\right)$.

An immediate consequence of (3.5) is

$$
\begin{equation*}
\tilde{\Phi}_{\omega, v}^{A}(\zeta, H ; \partial q)=q(\lambda+i v) \tilde{\Phi}_{\omega, v}^{A}(\zeta, H) \text { for all } H \in \mathrm{t}^{\prime}(\zeta), q \in I\left(\mathrm{t}_{\mathbf{c}}\right) . \tag{3.6}
\end{equation*}
$$

Lemma 3.7: Given any $u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$, there exist constants $c, r$ so that $\left|\tilde{\Phi}_{\omega, v}^{A}(\zeta, H ; \partial u)\right| \leq c\left(1+\left\|H_{R}\right\|\right)^{r}$ for all $H=H_{I}+H_{R} \in \mathrm{t}^{\prime}(\zeta)$.

Proof: By results of Harish-Chandra [2b], such an estimate is valid for $\tilde{\Phi}_{\omega, v}(\zeta, H)$. This implies that $c_{s}(F)=0$ for any $s \in W$ for which $\operatorname{Re}(s(\lambda$ $+i v)(H)>0$ for any $H \in F$. Using (3.5), then, the estimate holds for $\tilde{\Phi}_{\omega, v}^{A}(\zeta, H)$.

Now fix $\beta \in \Phi_{R}(\zeta)$, and use the notation of (2.6). Let $\Omega_{0}$ be a relatively compact open subset of $\mathrm{t}_{\beta}^{0}(\zeta)$.

Lemma 3.8: For all $u \in S\left(\mathrm{t}_{\mathrm{c}}\right), H_{0} \in \Omega_{0}$,

$$
\begin{aligned}
\tilde{\Phi}_{\omega, v}^{A}\left(\zeta, H_{0} ; \partial u\right)^{+} & -\tilde{\Phi}_{\omega, v}^{A}\left(\zeta, H_{0} ; \partial u\right)^{-}= \\
& =n_{\beta}(A) \lim _{\theta \rightarrow 0} \tilde{\Phi}_{\omega, v}^{A_{\beta}}\left(\zeta, H_{0}+\theta\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right) ; \partial \Lambda\left(u-s_{\beta} u\right)\right)
\end{aligned}
$$

where the limits exist uniformly for $H_{0} \in \Omega_{0}$.
Proof: Let $F$ and $s_{\beta} F$ be components of $\Omega(\zeta)$ with $H_{0} \in \bar{F} \cap s_{\beta} \bar{F}$ and $H_{0}+t H_{\beta}^{\prime} \in F$ for $t>0$ and sufficiently small. Write $c_{s}^{+}=c_{s}(F), c_{s}^{-}$ $=c_{s}\left(s_{\beta} F\right), s \in W$. Using (3.5),

$$
\begin{aligned}
\tilde{\Phi}_{\omega, v}^{A}\left(\zeta, H_{0} ; \partial u\right)^{ \pm}= & \sum_{s \in \vec{W}_{0}}\left[c_{s}^{ \pm} c\left(B_{s}, A\right) u(s(\lambda+i v))+\right. \\
& \left.+c_{s_{\beta s}}^{ \pm} c\left(B_{s_{\beta} s}, A\right) s_{\beta} u(s(\lambda+i v))\right] \exp \left(s(\lambda+i v)\left(H_{0}\right)\right)
\end{aligned}
$$

where $W_{0}$ is a set of coset representatives for $\left\{I, s_{\beta}\right\} \backslash W$. If $\left.\beta\right|_{a_{1}}=0$ so that $T_{\beta} \subseteq L$, we can use (3.5) directly to obtain a similar expression for $\tilde{\Phi}_{\omega, v}^{A_{\beta}}$ on $T_{\beta}^{\prime}$. However, for the general case we must combine (3.5) and (3.4) to see that there are constants $d_{s}, s \in W$, such that for all $H$ in an open subset of $\mathrm{t}_{\beta}$ containing $H_{0}, \tilde{\Phi}_{\omega, v}^{A_{\beta}}(\zeta, H)=\sum_{s \in W} d_{s} c\left(\widetilde{B}_{s}, A_{\beta}\right) \exp (\Lambda s(\lambda$ $+i v)(H))$ where $d_{s}=0$ unless $s A_{1} \subseteq\left(T_{\beta}\right)_{R}$ and in that case $\widetilde{B}_{s}$ is the orthogonal complement in $\left(T_{\beta}\right)_{R}$ of $s A_{1}$. (If no conjugate of $T_{\beta}$ is contained in $L$, then of course $d_{s}=0$ for all $s \in W$.) From work of Hirai [4] and the observations of Arthur in [1c, Thm. 9.1] it is known that $\tilde{\Phi}_{\omega, v}$ is continuous at $H_{0}$ and that

$$
\begin{aligned}
& \tilde{\Phi}_{\omega, v}\left(\zeta, H_{0} ; \partial H_{\beta}^{\prime}\right)^{+}-\tilde{\Phi}_{\omega, v}\left(\zeta, H_{0} ; \partial H_{\beta}^{\prime}\right)^{-}= \\
&=2 \lim _{\theta \rightarrow 0} \tilde{\Phi}_{\omega, v}\left(\zeta, H_{0}+\theta\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right) ; \partial \Lambda H_{\beta}^{\prime}\right)
\end{aligned}
$$

Thus we see that for all $s \in W_{0}$,
(i) $c_{s}^{+}+c_{s_{\beta s}}^{+}-c_{s}^{-}-c_{s_{\beta s}}^{-}=0$ and that
(ii) $c_{s}^{+}-c_{s_{\beta s}}^{+}-c_{s}^{-}+c_{s_{\beta} s}^{-}=2\left(d_{s}-d_{s_{\beta} s}\right)$.

By considering separately the cases that $s_{\beta} u=u$ and $s_{\beta} u=-u, u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$, it will be enough to prove that for all $s \in W_{0}$
(iii) $\left(c_{s}^{+}-c_{s}^{-}\right) c\left(B_{s}, A\right)+\left(c_{s_{\beta} s}^{+}-c_{s_{\beta s} s}^{-}\right) c\left(B_{s_{\beta} s}, A\right)=0$ and that
(iv) $\left(c_{s}^{+}-c_{s}^{-}\right) c\left(B_{s}, A\right)-\left(c_{s_{\beta s}}^{+}-c_{s_{\beta s}}^{-}\right) c\left(B_{s_{\beta s}}, A\right)=$

$$
=2 n_{\beta}(A)\left(d_{s}-d_{s_{\beta} S}\right) c\left(\tilde{B}_{s}, A_{\beta}\right)
$$

Suppose first that $s A_{1} \nsubseteq T_{R}$. Then also $s_{\beta} s A_{1} \nsubseteq T_{R}$ as $s_{\beta} T_{R}=T_{R}$, so that $c_{s}^{ \pm}=c_{s_{\beta s}}^{ \pm}=d_{s}=d_{s_{\beta s}}=0$. If $s A_{1} \subseteq T_{R}$ and $\left.\beta\right|_{s a_{1}} \neq 0$, then
$s A_{1} \nsubseteq\left(T_{\beta}\right)_{R}$, and again the same is true of $s_{\beta} s$, so that $c_{s}^{+}=c_{s}^{-}$, $c_{s_{\beta} s}^{+}=c_{s_{\beta}}^{-}$, and $d_{s}=d_{s_{\beta} s}=0$. Finally, suppose that $s A_{1} \subseteq T_{R}$ and $\left.\beta\right|_{s_{a_{1}}}$ $=0$. Then $s_{\beta} s A_{1}=s A_{1}$ so that $B_{s}=B_{s_{\beta} s}$. Also $\exp \left(H_{\beta}^{\prime}\right) \in B_{s}$ so that using (3.1), $c\left(B_{s}, A\right)=n_{\beta}(A) c\left(\left(B_{s}\right)_{\beta}, A_{\beta}\right)$. But since $\left.\beta\right|_{s a_{1}}=0,\left(B_{s}\right)_{\beta}=\widetilde{B}_{s}$. Thus (iii) and (iv) are satisfied in all cases.

## §4. Distribution-valued functions on $t$

In [1c], to prove (1.2) Arthur shows that for a fixed matrix coefficient $f$ of the discrete series representation $\pi$ and for fixed $\zeta \in Z(t)$,

$$
\psi(H)=\tilde{\Delta}(\zeta, H)\left[r_{f}^{A}(\zeta \exp H)-\varepsilon(T, A)(-1)^{p}\left\langle\theta_{\pi}, f\right\rangle \theta_{\pi}(\zeta \exp H)\right]
$$

is a smooth function of $H \in \mathrm{t}^{\prime}(\zeta)$ which is an eigenfunction of $\partial q$ for all $q \in I\left(\mathrm{t}_{\mathbf{c}}\right)$, extends to a continuously differentiable function in a neighborhood of any $H_{0} \in \mathfrak{t}_{\beta}^{0}(\zeta), \beta \in \Phi_{R}(\zeta)$, and is of moderate growth. Then using techniques of Harish-Chandra he shows that any such function must be zero.

In our situation, in order to obtain a differential equation for $\partial q$, $q \in I\left(\mathrm{t}_{\mathbf{c}}\right)$, we must consider functions $\psi$ not only of $H \in \mathrm{t}^{\prime}(\zeta)$, but also of the $\alpha \in C_{c}^{\infty}(\mathscr{F})$ which are used to form the wave packets $f=\varphi_{\alpha}$. In this section we will give sufficient conditions on such a function $\psi(H: \alpha)$ to guarantee that $\psi=0$. Then in $\S 5$ we will prove (1.4) by showing that

$$
\begin{aligned}
& \psi(H: \alpha)=\tilde{\Delta}(\zeta, H)\left[r_{\varphi_{\alpha}}^{A}(\zeta \exp H)-\varepsilon\left(T, A, A_{1}\right)(-1)^{p}[W(\omega)]^{-1}\right. \\
&\left.\quad \int_{\mathscr{F}}\left\langle\theta_{\omega, v}, \varphi_{\alpha}\right\rangle \theta_{\omega, v}^{A}(\zeta \exp H) d v\right]
\end{aligned}
$$

satisfies these conditions.
For simplicity we assume that $T \subseteq L$. We also assume that $T$ is not a fundamental Cartan subgroup of $L$. Fix $\zeta \in Z(t)$ and $\lambda \in t_{M, c}^{*}$ corresponding to the infinitesimal character of some $\omega \in \varepsilon_{2}(M)$. Let $V$ be a subspace of $\mathscr{F}$ and $U \subseteq V$ any open subset of $V$. For $q \in I\left(\mathrm{t}_{\mathbf{c}}\right)$, let $p(q)$ be the polynomial on $U$ given by $p(q: v)=q(\lambda+i v), v \in U$. For $v \in S\left(\mathrm{t}_{\mathbf{c}}\right)$ and $s \in W$, let $p_{s}(v)$ be the polynomial on $U$ given by $p_{s}(v: v)=v(s(\lambda+i v))$, $v \in U$. Let $\rho_{I}=\frac{1}{2} \sum_{\beta \in \Phi_{I}^{+} \beta}$.

Define $E(U)$ to be the complex vector space consisting of all functions $\psi$ on $\mathrm{t}^{\prime}(\zeta) \times C_{c}^{\infty}(U)$ satisfying:
(4.1) for each $\alpha \in C_{c}^{\infty}(U), \psi(H: \alpha)=e^{\rho_{I}(H)} f_{\alpha}(\zeta \exp H)$ where $f_{\alpha}$ is a smooth function on $T^{\prime}$;
(4.2) for each $q \in I\left(\mathrm{t}_{\mathbf{c}}\right) . \psi(H ; \partial q: \alpha)=\psi(H: p(q) \alpha)$ for all $H \in \mathrm{t}^{\prime}(\zeta)$, $\alpha \in C_{c}^{\infty}(U) ;$
(4.3) for each $\beta \in \Phi_{R}(\zeta), H_{0} \in \mathrm{t}_{\beta}^{0}(\zeta), \psi(H: \alpha)$ extends to a smooth function in a neighborhood of $H_{0}$ for all $\alpha \in C_{c}^{\infty}(U)$;
(4.4) for all $\alpha \in C_{c}^{\infty}(U), \psi(H: \alpha)$ extends to a $C^{\infty}$ function on $\Omega_{I}=\mathrm{t}_{I}$ $+\left\{H \in \mathfrak{t}_{R}: \beta(H) \neq 0\right.$ for any $\beta \in \Phi$ with $\left.\left.\beta\right|_{\mathrm{t}_{R}} \neq 0\right\} ;$
(4.5) for each fixed $H \in \mathrm{t}^{\prime}(\zeta), u \in S\left(\mathrm{t}_{\mathbf{c}}\right), \alpha \mapsto \psi(H ; \partial u: \alpha)$ defines a distribution on $U$. Further, for any $u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$ there is a continuous seminorm $\mu$ on $C_{c}^{\infty}(U)$ and a constant $r$ so that

$$
\begin{aligned}
& |\psi(H ; \partial u: \alpha)| \leq \mu(\alpha)(1+L(\zeta \exp H))^{p}\left(1+\left\|H_{R}\right\|\right)^{r} \text { for all } \\
& H=H_{I}+H_{R} \in \mathrm{t}^{\prime}(\zeta), \alpha \in C_{c}^{\infty}(U) .
\end{aligned}
$$

We are of course primarily interested in showing that $E(\mathscr{F})=\{0\}$. However, in order to do this, it is necessary to use the various spaces $E(U)$ defined above. Note that when $U \subseteq U^{\prime}$ are open subsets of $V$, then for $\psi \in E\left(U^{\prime}\right)$, the restriction of $\psi$ to $\mathrm{t}^{\prime}(\zeta) \times C_{c}^{\infty}(U)$ is an element of $E(U)$. For $S$ a subalgebra of $S\left(\mathrm{t}_{\mathbf{c}}\right), s \in W$, and $U \subseteq V \subseteq \mathscr{F}$ as above, define $E(U: s: S)=\left\{\psi \in E(U): \psi(H ; \partial v: \alpha)=\psi\left(H: p_{s}(v) \alpha\right)\right.$ for all $v \in S, H \in \mathfrak{t}^{\prime}(\zeta)$, $\left.\alpha \in C_{c}^{\infty}(U)\right\}$. When $S=S\left(\mathrm{t}_{\mathbf{c}}\right)$, we write $E\left(U: s: S\left(\mathrm{t}_{\mathbf{c}}\right)\right)=E(U: s)$.

Lemma 4.6: Let $U$ be an open subset of a subspace $V$ of $\mathscr{F}$. Let $\psi \in E(U: s)$ for some $s \in W$ and let $\Omega$ be a convex open subset of $t$ on which $\psi$ extends to a smooth function and such that $L(\zeta \exp H)$ is bounded on compact subsets of $\Omega$. Then there is a fixed distribution $T$ on $U$ so that $\psi(H: \alpha)=T\left(\exp \left(p_{s}(H)\right) \alpha\right)$ for all $H \in \Omega, \alpha \in C_{c}^{\infty}(U)$.

Proof: Let $P$ be a fixed point in $\Omega$ and fix $\alpha \in C_{c}^{\infty}(U)$. For any $H_{0} \in \Omega$, let $H=H_{0}-P$. Then since $\Omega$ is convex, $P+t H \in \Omega, 0 \leq t \leq 1$, and using Taylor's theorem, for any $q>0$ there is a $0<\tau<1$ with

$$
\begin{aligned}
& \psi\left(H_{0}: \alpha\right)=\sum_{r=0}^{q-1} \frac{\psi\left(P ; \partial H^{r}: \alpha\right)}{r!}+\frac{\psi\left(P+\tau H ; \partial H^{q}: \alpha\right)}{q!} \\
& =\psi\left(P:\left(\sum_{r=0}^{q-1} \frac{p_{s}(H)^{r}}{r!}\right) \alpha\right)+\psi\left(P+\tau H: p_{s}(H)^{q} / q!\alpha\right)
\end{aligned}
$$

Using (4.5) and the assumption that $L(\zeta \exp H)$ is bounded on compact subsets of $\Omega$, there is a constant $C$ so that for all $q \geq 0, \mid \psi(P$ $\left.+\tau H: p_{s}(H)^{q} \alpha\right) \mid / q!\leq C \mu\left(\alpha p_{s}(H)^{q} / q!\right)$ where $\mu$ is a continuous seminorm on $C_{c}^{\infty}(U)$. But as $q$ goes to $\infty, \alpha p_{s}(H)^{q} / q$ ! converges to zero and $\alpha \sum_{r=0}^{q-1} p_{s}(H)^{r} / r!$ converges to $\alpha \exp p_{s}(H)$ in $C_{c}^{\infty}(U)$ so that $\psi\left(H_{0}: \alpha\right)$
$=\psi\left(P: \exp \left(p_{s}(H)\right) \alpha\right)$. Thus if we let $T(\alpha)=\psi\left(P: \exp \left(-p_{s}(P)\right) \alpha\right)$, we see that $\psi\left(H_{0}: \alpha\right)=T\left(\exp \left(p_{s}\left(H_{0}\right)\right) \alpha\right)$.

As before, $U$ is an open subset of a subspace $V$ of $\mathscr{F}$. Via duality, we think of $V$ also as a subspace of $\mathrm{t}_{R}$.

Lemma 4.7: Let $s \in W$ with $s V \subseteq \mathrm{t}_{\mathrm{R}}$. Then $E(U: s)=\{0\}$.
Proof: Since $\lambda \in \mathrm{t}_{\boldsymbol{M}, \mathrm{c}}^{*}$ corresponds to the infinitesimal character of some $\omega \in \varepsilon_{2}(M)$, we know that $\langle\lambda, \beta\rangle \neq 0$ for every $\beta \in \Phi_{M}=\left\{\beta \in \Phi:\left.\beta\right|_{a_{1}}\right.$ $=0\}$. Suppose that $\left.s \lambda\right|_{a_{1}}=0$. Then using [3a] $s \lambda$ is also regular with respect to $\Phi_{M}$. We have assumed that $T$ is not a fundamental Cartan subgroup of $L$ and that $P$ is a cuspidal parabolic subgroup of $G$. Thus $\Phi_{M}$ contains real roots so that $\left.s \lambda\right|_{t_{M, R}} \neq 0$. Since $\mathrm{t}_{R}=\mathfrak{a}_{1} \oplus \mathrm{t}_{M, R}$, we see in any case that $\left.s \lambda\right|_{t_{R}} \neq 0$. But considered as an element of $\mathrm{t}_{\mathbf{C}}^{*}, \lambda \in i \mathrm{t}_{I}^{*}+\mathrm{t}_{\boldsymbol{R}}^{*}$ $=\left\{\mu \in \mathrm{t}_{\mathbf{C}}^{*}:\left.\mu\right|_{\mathrm{t}_{\boldsymbol{I}}}\right.$ takes pure imaginary values and $\left.\mu\right|_{\mathrm{t}_{\boldsymbol{R}}}$ takes real values $\}$. Since this real subspace of $\mathrm{t}_{\mathbf{c}}^{*}$ is stable under $W, s \lambda$ takes real values on $\mathrm{t}_{\mathrm{R}}$.

Let $t_{2}$ be the orthogonal complement of $s V$ in $t_{R}$. For all $H \in t_{2}$, $p_{s}(H: v)=s(\lambda+i v)(H)=s \lambda(H)$ is independent of $v \in V$. Since $\left.s \lambda\right|_{t_{R}} \neq 0$ and $\left.s \lambda\right|_{s V}=0$, we can choose $H_{2} \in \mathrm{t}_{2}$ with $s \lambda\left(H_{2}\right) \neq 0$ and $\beta\left(H_{2}\right) \neq 0$ for every $\beta \in \Phi_{R}(\zeta)$ for which $\left.\beta\right|_{t_{2}} \neq 0$. Let $\mathrm{t}_{1}=\left\{H \in \mathrm{t}:\left\langle H, H_{2}\right\rangle=0\right\}$. Fix $H_{1} \in \mathrm{t}_{1}$ so that for $t \in \mathbf{R}, H_{1}+t H_{2} \in \mathrm{t}^{\prime}(\zeta)$ for all but finitely many values of $t$, and so that $H_{1}+t H_{2} \in \bigcup_{\beta \in \Phi_{R}(\zeta)} \mathfrak{t}_{\beta}^{0}(\zeta)$ whenever $H_{1}+t H_{2} \notin \mathrm{t}^{\prime}(\zeta)$.

Fix $\beta \in \Phi_{R}(\zeta)$ and $t_{0} \in \mathbf{R}$ with $H_{0}=H_{1}+t_{0} H_{2} \in \mathfrak{t}_{\beta}^{0}(\zeta)$. Let $\psi \in E(U: s)$. By (4.6) there are distributions $T^{ \pm}$so that for $t>0$ and small enough that $H_{0} \pm t H_{2} \in \mathrm{t}^{\prime}(\zeta) ; \psi\left(H_{0} \pm t H_{2}: \alpha\right)=T^{ \pm}\left(\alpha \exp p_{s}\left(H_{0} \pm t H_{2}\right)\right)=$ $=c^{ \pm}(\alpha) \exp \left(t_{0} \pm t\right)\left(s \lambda\left(H_{2}\right)\right) \quad$ where for all $\quad \alpha \in C_{c}^{\infty}(U), \quad c^{ \pm}(\alpha)=$ $=T^{ \pm}\left(\alpha \exp p_{s}\left(H_{1}\right)\right)$. By the continuity of $\psi$ at $H_{0}, c^{+}(\alpha)=c^{-}(\alpha)$ for all $\alpha \in C_{c}^{\infty}(U)$.

Since we can do this for any value of $t_{0}$ with $H_{1}+t_{0} H_{2} \notin t^{\prime}(\zeta)$, we see that for any $\alpha \in C_{c}^{\infty}(U)$ there is a constant $c(\alpha)$ so that $\psi\left(H_{1}+t H_{2}: \alpha\right)$ $=c(\alpha) e^{t s \lambda\left(H_{2}\right)}$ for all $t \in \mathbf{R}$. But since $s \lambda\left(H_{2}\right)$ is real-valued and non-zero, this contradicts the growth condition on $\psi$ unless $c(\alpha)=0$. For fixed $H_{2}$ as above, the set of points $H_{1}+t H_{2}$ with $t \in \mathbf{R}$ and $H_{1} \in \mathfrak{t}_{1}$ satisfying the above hypotheses is dense in $\mathrm{t}^{\prime}(\zeta)$. Thus $\psi(H: \alpha)=0$ for all $H \in \mathrm{t}^{\prime}(\zeta)$, $\alpha \in C_{c}^{\infty}(U)$.

For $V$ a subspace of $\mathscr{F}$, let $\Phi_{V}=\{\beta \in \Phi:\langle\beta, v\rangle=0$ for all $v \in V\}$. Let $V^{\prime}=\left\{v \in V:\langle\beta, v\rangle \neq 0\right.$ for all $\left.\beta \in \Phi \backslash \Phi_{V}\right\}$.

I emma 4.8: Let $s \in W$ with $s V \nsubseteq \mathrm{t}_{R}$. Then for all $v \in V^{\prime},\left.s v\right|_{\mathrm{t}_{I}} \neq 0$.

Proof: Fix $s \in W$ and assume that $\left.s v\right|_{t_{I}}=0$ for some $v \in V^{\prime}$. Then $v, s v \in \mathrm{t}_{R}^{*}=\left\{\mu \in \mathrm{t}^{*}:\left.\mu\right|_{\mathrm{t}_{I}}=0\right\}$. Let $W_{1}=\left\{s_{1} \in W: s_{1} \mathrm{t}_{R}=\mathrm{t}_{R}\right\}$. Then for every $\beta \in \Phi_{R} \cup \Phi_{I}, s_{\beta} \in W_{1}$. Also if $\gamma \in \Phi_{c}$ with $\left\langle\gamma, \gamma^{\sigma}\right\rangle=0$, then $s_{\gamma} s_{\gamma}^{\sigma} \in W_{1}$. As in [3a] it is easy to see that there is $s_{1} \in W_{1}$ so that $v, s_{1} s v$ are separated only by hyperplanes corresponding to roots $\gamma \in \Phi_{c}$ with $\left\langle\gamma, \gamma^{\sigma}\right\rangle>0$. Thus there are $\gamma_{1}, \ldots, \gamma_{k} \in \Phi_{c}$ so that $\left\langle\gamma_{i}, \gamma_{i}^{\sigma}\right\rangle>0,1 \leq i \leq k$, and $v=s_{\gamma_{1}} \ldots s_{\gamma_{k}} s_{1} s v$. But since $v \in V^{\prime}$, this implies that $s_{\gamma_{1}} \ldots s_{\gamma_{k}} s_{1} s V=V$ and $s V=s_{1}^{-1} s_{\gamma_{k}} \ldots s_{\gamma_{1}} V$. For $1 \leq i \leq k,\left\langle\gamma_{i}, \gamma_{i}^{\sigma}\right\rangle>0$ implies that $\gamma_{i}-\gamma_{i}^{\sigma}$ $=\beta_{i} \in \Phi_{I}$ so that $\gamma_{i}=\gamma_{R}+\beta_{i} / 2$ for some $\gamma_{R} \in \mathrm{t}_{R}^{*}$. Thus $s_{\gamma_{k}} \ldots s_{\gamma_{1}} V \subseteq V$ $+\sum_{i=1}^{k} \mathbf{R} \gamma_{i} \subseteq \mathrm{t}_{R}+\sum_{i=1} \mathbf{R} \beta_{i}$. But for $s_{1} \in W_{1}, s_{1}^{-1}\left(\mathrm{t}_{R}+\sum_{i=1}^{k} \mathbf{R} \beta_{i}\right) \subseteq \mathrm{t}_{R}$ $+\sum_{\beta \in \Phi_{I}} \mathbf{R} \beta$. Thus $s V \subseteq \mathrm{t}_{R}+\sum_{\beta \in \Phi_{I}} \mathbf{R} \beta$. Since $s V \nsubseteq \mathrm{t}_{R}$, there is $\beta \in \Phi_{I}$ with $\left.\beta\right|_{s V} \neq 0$. Thus $s^{-1} \beta \in \Phi \backslash \Phi_{V}$ so that $\langle\beta, s v\rangle \neq 0$ since $v \in V^{\prime}$. This contradicts the assumption that $\left.s v\right|_{t_{I}}=0$.

Lemma 4.9: Suppose $s \in W$ with $s V \nsubseteq \mathrm{t}_{R}$. Then for any open subset $U$ of $V^{\prime}, E(U: s)=\{0\}$.

Proof: Define $\Omega_{I}$ as in (4.4). Clearly $L(\zeta \exp H)$ is bounded for $H$ in compact subsets of $\Omega_{I}$ since for $\beta \in \Phi$ with $\left.\beta\right|_{a} \neq 0, \xi_{\beta}(\zeta \exp H) \neq 1$ for all $H \in \Omega_{I}$. Let $F$ be a connected component of $\Omega_{I}$. Then by (4.6), for $\psi \in E(U: s)$ there is a distribution $T$ on $U$ so that $\psi(H: \alpha)$ $=T\left(\alpha \exp p_{s}(H)\right) \quad$ for $\quad$ all $\quad H \in F, \quad \alpha \in C_{c}^{\infty}(U)$. By (4.1) $\quad \psi(H: \alpha)$ $=e^{\rho_{I}(H)} f_{\alpha}(\zeta \exp H)$ for some smooth function $f_{\alpha}$ defined on $T^{\prime}$. Let $H_{0} \in L=\left\{H \in \mathrm{t}_{I}: \exp (H / 2)=1\right\}$. Then for all $H \in F, H+H_{0} \in F$ and $\psi(H: \alpha)=\psi\left(H+H_{0}: \alpha\right)$ so that $T\left(\exp p_{s}(H)\left(1-\exp p_{s}\left(H_{0}\right)\right) \alpha\right)=0$. Since $\exp \left(-p_{s}(H)\right) \in C^{\infty}(U)$, this implies that for all $\alpha \in C_{c}^{\infty}(U)$ and $H_{0} \in L, T((1$ $\left.\left.-\exp p_{s}\left(H_{0}\right)\right) \alpha\right)=0$.
Because $s \lambda$ takes pure imaginary values on $\mathrm{t}_{I}$ and $\operatorname{siv}, v \in U$, takes real values on $\mathfrak{t}_{I}, \exp \left(p_{s}\left(H_{0}\right)\right)=1$ only if $s v\left(H_{0}\right)=0$. Fix $v_{0} \in U$. Since $v_{0} \in V^{\prime}$, $\left.s v_{0}\right|_{t_{I}} \neq 0$ by (4.8). Since $L$ spans $\mathrm{t}_{I}$, there is $H_{0} \in L$ with $s v_{0}\left(H_{0}\right) \neq 0$. Let $U_{0}=\left\{v \in U: \operatorname{sv}\left(H_{0}\right) \neq 0\right\}$. Then $U_{0}$ is an open neighborhood of $v_{0}$ in $U$ and $\left(1-\exp p_{s}\left(H_{0}\right)\right)^{-1} \in C^{\infty}\left(U_{0}\right)$, so that for any $\alpha \in C_{c}^{\infty}(U)$ with support contained in $U_{0}, T(\alpha)=0$. Thus $v_{0}$ is not in the support of $T$ and since $v_{0} \in U$ was arbitrary, $T=0$.

For a subspace $V$ of $\mathscr{F}$ and $s \in W$, let
$W(s V)=\{w \in W: w s(\lambda+i v)=s(\lambda+i v)$ for all $v \in V\}=\{w \in W: w s \lambda=s \lambda$ and $w s v=s v$ for all $v \in V\}$ and $S(s V)=\left\{v \in S\left(\mathrm{t}_{\mathbf{c}}\right): w v=v\right.$ for all $w \in W(s V)\}$.

Lemma 4.10: For $U$ any open subset of $V^{\prime}$ and for all $s \in W$, $E(U: s: S(\mathrm{sV}))=\{0\}$.

Proof: We will show that $E(U: s: S(s v)) \subseteq E(U: s)$ which is zero by (4.7) and (4.9).

Let $\mathrm{t}_{0}=\left\{H \in \mathrm{t}_{\mathbf{c}}: s \lambda(H)=0\right.$ and $s v(H)=0$ for all $\left.v \in V\right\}$. Clearly for $v \in S\left(\mathrm{t}_{0}\right)$, if $v$ has no constant term, then $p_{s}(v: v)=v(s(\lambda+i v))=0$ for all $v \in U$ so that $p_{s}(v)=0$ as an element of $C^{\infty}(U)$. Let $t_{1}=\mathbf{C}(s \lambda) \oplus \mathbf{C}(s V)$. Then $\mathrm{t}_{1}$ is the orthogonal complement in $\mathrm{t}_{\mathbf{c}}$ of $\mathrm{t}_{0}$ so that $S\left(\mathrm{t}_{\mathbf{c}}\right)=$ $S\left(\mathrm{t}_{0}\right) \otimes S\left(\mathrm{t}_{1}\right)$ and $S\left(\mathrm{t}_{1}\right) \subseteq S(s V)$. Thus to show that $E(U: s: S(s V)) \subseteq E(U: s)$ it is enough to show that for all $v \in S\left(\mathrm{t}_{0}\right), \psi \in E(U: s: S(s V))$,

$$
\begin{equation*}
\psi(H, \partial v: \alpha)=\psi\left(H: p_{s}(v) \alpha\right) \text { for all } H \in \mathrm{t}^{\prime}(\zeta), \alpha \in C_{c}^{\infty}(U) \tag{*}
\end{equation*}
$$

Let $I\left(\mathrm{t}_{0}\right)=\left\{v \in S\left(\mathrm{t}_{0}\right): w v=v\right.$ for all $\left.w \in W(s V)\right\} . W(s V)$ is the pointwise stabilizer in $W$ of $\mathrm{t}_{1}$ so that $W(s V)$ is generated by reflections in roots which vanish on $t_{1}$, that is roots lying in $t_{0}$. Thus using a standard argument of Harish-Chandra [2a], there are $u_{1}, \ldots, u_{k} \in S\left(\mathrm{t}_{0}\right), u_{i}$ homogeneous of degree $d_{i}, 1 \leq i \leq k$, so that each $v \in S\left(\mathrm{t}_{0}\right)$ can be written as $v=\sum_{i=1}^{k} u_{i} q_{i}$ for some $q_{1}, \ldots, q_{k} \in I\left(\mathrm{t}_{0}\right)$.

Let $d=\max \left\{d_{1}, \ldots, d_{k}\right\}$. Suppose $v \in S\left(\mathrm{t}_{0}\right)$ is homogeneous of degree $\ell>d$. Then each $q_{i}$ is homogeneous of degree $\ell-d_{i}>0$ so that $p_{s}\left(q_{i}\right)=0, \quad 1 \leq i \leq k, \quad$ and $\quad p_{s}(v)=\sum_{i=1}^{k} p_{s}\left(u_{i}\right) p_{s}\left(q_{i}\right)=0$. Thus for any $\quad \psi \in E(U: s: S(s V)), \quad \alpha \in C_{c}^{\infty}(U), \quad$ and $\quad H \in \mathfrak{t}^{\prime}(\zeta), \quad \psi(H ; \partial v: \alpha)=$ $=\sum_{i=1}^{k} \psi\left(H ; \partial u_{i}: p_{s}\left(q_{i}\right) \alpha\right)=0=\psi\left(H: p_{s}(v) \alpha\right)$.

Now let $v_{0} \in S\left(\mathrm{t}_{0}\right)$ be homogeneous of degree $k, 1 \leq k \leq d$, and assume inductively that for $v \in S\left(\mathrm{t}_{0}\right)$ homogeneous of degree greater than $k$ and $\psi \in E(U: s: S(s V))$, property $\left(^{*}\right)$ holds. For $\psi \in E(U: s: S(s V))$, define $v_{0} \psi$ by $v_{0} \psi(H: \alpha)=\psi\left(H ; \partial v_{0}: \alpha\right)$ for $H \in t^{\prime}(\zeta), \quad \alpha \in C_{c}^{\infty}(U)$. Clearly $v_{0} \psi \in E(U: s: S(s V))$. Further, if $v \in S\left(\mathrm{t}_{0}\right)$ is homogeneous of degree $\geq 1$, then $v_{0} \psi(H ; \partial v: \alpha)=\psi\left(H ; \partial\left(v v_{0}\right): \alpha\right)=\psi\left(H: p_{s}\left(v v_{0}\right) \alpha\right)=0=$ $v_{0} \psi\left(H: p_{s}(v) \alpha\right)$ by the induction hypothesis. If $v \in S\left(\mathrm{t}_{0}\right)$ is constant, $v \in I\left(\mathrm{t}_{0}\right)$ so that also in this case $v$ and $v_{0} \psi$ satisfy $\left(^{*}\right)$. Thus $v_{0} \psi \in E(U: s)$ so that $v_{0} \psi=0$; that is, $\psi\left(H ; \partial v_{0}: \alpha\right)=0=\psi\left(H: p_{s}\left(v_{0}\right) \alpha\right)$ for all $H \in \mathrm{t}^{\prime}(\zeta)$, $\alpha \in C_{c}^{\infty}(U)$. Thus for any $v_{0} \in S\left(\mathrm{t}_{0}\right), v_{0}$ homogeneous of degree $\geq 1$, and $\psi \in E(U: s: S(s V)), \psi$ and $v_{0}$ satisfy $\left(^{*}\right)$. Again, since $\left({ }^{*}\right)$ always holds for terms of degree 0 , we are done.

Let $U$ be an open subset of $\mathscr{F}$. For $\psi \in E(U)$ and $u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$, define $u \psi(H: \alpha)=\psi(H ; \partial u: \alpha)$. For each $f \in C^{\infty}(U), \psi \in E(U)$, define $f \psi(H: \alpha)$ $=\psi(H: f \alpha)$. Clearly the above give algebra actions of $S\left(\mathrm{t}_{\mathbf{c}}\right)$ and $C^{\infty}(U)$ on $E(U)$ which commute. Thus $Y(U)=C^{\infty}(U) \otimes S\left(\mathrm{t}_{\mathbf{c}}\right)$ acts on $E(U)$. For $y=\sum_{i=1}^{k} f_{i} \otimes u_{i} \in Y(U)$ and $s \in W$, define $s y=\sum_{i=1}^{k} f_{i} \otimes s u_{i}$ and define $p_{s}(y)$ to be the $C^{\infty}$ function on $U$ given by $p_{s}(y: v)=\sum_{i=1}^{k} f_{i}(v) p_{s}\left(u_{i}: v\right)$, $v \in U$. Define $\quad Y_{0}(U)=\left\{y \in Y(U): p_{s}(y)=0 \quad\right.$ for all $\left.s \in W\right\}, \quad Y^{I}(U)$ $=C^{\infty}(U) \otimes I\left(\mathrm{t}_{\mathbf{c}}\right)$, and $Y_{0}^{I}(U)=Y_{0}(U) \cap Y^{I}(U)$.

Lemma 4.11: $Y_{0}(U)=\left\{\sum_{i=1}^{k} v_{i} y_{i}: v_{i} \in S\left(\mathrm{t}_{\mathbf{c}}\right), y_{i} \in Y_{0}^{I}(U)\right\}$.
Proof: We know from [2a] that there are homogeneous elements $u_{1}, \ldots, u_{w} \in S\left(\mathrm{t}_{\mathbf{c}}\right), w=[W]$, so that each $u \in S\left(\mathrm{t}_{\mathbf{c}}\right)$ can be written uniquely as $u=\sum_{i=1}^{w} u_{i} q_{i}$ where $q_{i} \in I\left(\mathrm{t}_{\mathbf{c}}\right), 1 \leq i \leq w$. Write $W=\left\{s_{1}, \ldots, s_{w}\right\}$ and $p_{s_{i}}=p_{i}, 1 \leq i \leq w$. Fix $v \in U \cap \mathscr{F}^{\prime}$. Then $\{s(\lambda+i v): s \in W\}$ is a set of $w$ distinct points in $\mathrm{t}_{\mathbf{c}}^{*}$. Thus there are polynomials $v_{1}, \ldots, v_{w} \in S\left(\mathrm{t}_{\mathbf{c}}\right)$ so that $p_{i}\left(v_{j}: v\right)=v_{j}\left(s_{i}(\lambda+i v)\right)=\delta_{i j}, \quad 1 \leq i, j \leq w$. For $1 \leq j \leq w$, write $v_{j}$ $=\sum_{k=1}^{w} q_{k j} u_{k}$ where $q_{k j} \in I\left(\mathrm{t}_{\mathbf{c}}\right), 1 \leq k \leq w$. Then for $1 \leq i, j \leq w, \delta_{i j}$ $=p_{i}\left(v_{j}: v\right)=\sum_{k=1}^{w} p\left(q_{k j}: v\right) p_{i}\left(u_{k}: v\right)$. Thus if $A_{v}$ is the $w \times w$ matrix with entries $a_{i j}(v)=p_{i}\left(u_{j}: v\right), 1 \leq i, j \leq w$, we see that $A_{v}$ is invertible so that $\operatorname{det} A_{v} \neq 0$.

Now let $y=\sum_{i=1}^{k} f_{i} \otimes v_{i}$ denote an arbitrary element of $Y_{0}(U)$. For $1 \leq i \leq k$, write $v_{i}=\sum_{j=1}^{w} q_{i j} u_{j}$ where $q_{i j} \in I\left(\mathrm{t}_{\mathbf{c}}\right)$ and $u_{j}$ are as above, $1 \leq j \leq w$. Then we can write $y=\sum_{j=1}^{w} u_{j} y_{j}$ where $y_{j}$ $=\sum_{i=1}^{k} f_{i} \otimes q_{i j} \in Y^{I}(U)$ for $1 \leq j \leq w$. Since $y \in Y_{0}(U)$, for all $1 \leq i \leq w$, $v \in U, p_{i}(y: v)=\sum_{j=1}^{w} p\left(y_{j}: v\right) p_{i}\left(u_{j}: v\right)=0$. Now since for each $v \in U \cap \mathscr{F}^{\prime}$ the matrix $A_{v}$ is non-singular, this implies that for $v \in U \cap \mathscr{F}^{\prime}, p\left(y_{j}: v\right)$ $=0,1 \leq j \leq w$. But $U \cap \mathscr{F}^{\prime}$ is dense in $U$ so that $p\left(y_{j}: v\right)=0,1 \leq j \leq w$, for all $v \in U$.

Lemma 4.12: For all $y \in Y_{0}(U), \psi \in E(U), y \psi=0$.
Proof: By (4.11) it is enough to show that $y \psi=0$ for all $y \in Y_{0}^{I}(U)$. Write $y=\sum_{i=1}^{k} f_{i} \otimes q_{i}$ where $q_{i} \in I\left(\mathrm{t}_{\mathbf{c}}\right), 1 \leq i \leq k$. Then for all $H \in \mathrm{t}^{\prime}(\zeta)$, $\alpha \in C_{c}^{\infty}(U), \quad y \psi(H: \alpha)=\sum_{i=1}^{k} \psi\left(H ; \partial q_{i}: f_{i} \alpha\right)=\sum_{i=1}^{k} \psi\left(H: p\left(q_{i}\right) f_{i} \alpha\right)=$ $\psi(H: p(y) \alpha)=0$.

Let $v_{0} \in \mathscr{F}$. Let $\Phi_{0}=\left\{\beta \in \Phi:\left\langle\beta, v_{0}\right\rangle=0\right\}, V=\{v \in \mathscr{F}:\langle\beta, v\rangle=0$ for all $\left.\beta \in \Phi_{0}\right\}$. Then $v_{0} \in V^{\prime}$. For $s \in W$, define $W(s V)$ and $S(s V)$ as in (4.10). Note that for $s \in W, v \in S(s V), s V$ and $p_{s}(v)$ depend only on the coset of $s$ in $W / W(V)$.

Lemma 4.13: There is a neighborhood $U$ of $v_{0}$ in $\mathscr{F}$ so that $E(U)$ $=\sum_{s \in W / W(V)} E(U: s: S(s V))$.

Proof: Let $s_{0}=1, s_{1}, \ldots, s_{k}$ be a set of representatives for the cosets $W(V) \backslash W$. For $0 \leq i \leq k$, write $p_{i}$ for $p_{s_{i}}$. Let $H_{0} \in \mathrm{t}_{\mathbf{c}}$ be dual to $\lambda+i v_{0}$. Then for $1 \leq i \leq k$, since $v_{0} \in V^{\prime}, p_{i}\left(H_{0}: v_{0}\right) \neq p_{0}\left(H_{0}: v_{0}\right)$. Let $U$ be a neighborhood of $v_{0}$ in $\mathscr{F}$ for which $p_{i}\left(H_{0}: v\right) \neq p_{0}\left(H_{0}: v\right)$ for all $v \in U$, $1 \leq i \leq k$. Then

$$
y_{1}=\prod_{i=1}^{k} \frac{H_{0}-p_{i}\left(H_{0}\right)}{p_{0}\left(H_{0}\right)-p_{i}\left(H_{0}\right)} \in Y(U)
$$

and $w y_{1}=y_{1}$ for all $w \in W(V)$. For any $w \in W(V)$,

$$
p_{w s_{i}}\left(y_{1}\right)=p_{s_{i}}\left(w^{-1} y_{1}\right)=p_{i}\left(y_{1}\right)=\left\{\begin{array}{l}
1 \text { if } i=0 \\
0 \text { if } 1 \leq i \leq k
\end{array}\right.
$$

Thus

$$
p_{s}\left(y_{1}\right)=\left\{\begin{array}{l}
1 \text { if } s \in W(V) \\
0 \text { if } s \notin W(V) .
\end{array}\right.
$$

Now for any $s, t \in W$,

$$
p_{s}\left(t y_{1}\right)=p_{t^{-1} s}\left(y_{1}\right)=\left\{\begin{array}{l}
1 \text { if } s \in t W(V) \\
0 \text { if } s \notin t W(V) .
\end{array}\right.
$$

Thus for

$$
y=\sum_{s \in W / W(V)} s y_{1} \in Y^{I}(U), p(y)=\sum_{s \in W / W(V)} p_{1}(s y)=1
$$

so that $y \psi=\psi$ for all $\psi \in E(U)$. But for $s \in W$ and $v \in S(s V)$, ( $v$ $\left.-p_{s}(v)\right)\left(s y_{1}\right) \in Y_{0}(U)$ so that for all $\psi \in E(U), s y_{1} \psi \in E(U: s: S(s V))$. Thus $\psi=\sum_{s \in W / W(V)} s y_{1} \psi$ gives the required decomposition.

Note that (4.13) and (4.10) do not combine to imply that every $v_{0} \in \mathscr{F}$ has a neighborhood $U$ in $\mathscr{F}$ so that $E(U)=\{0\}$. This is because in the statement of (4.10) the set $U$ is an open subset of $V^{\prime}$, not of $\mathscr{F}$, and unless $v_{0} \in \mathscr{F}^{\prime}, V$ is a proper subspace of $\mathscr{F}$.

Suppose $v_{0} \in \mathscr{F}^{\prime}$. Then $\Phi_{0}=\emptyset, V=\mathscr{F}$, and for all $s \in W, W(s V)=\{1\}$, $S(s V)=S\left(\mathrm{t}_{\mathbf{c}}\right)$. In the proof of (4.13) we could have picked the neighborhood $U$ of $v_{0}$ in $\mathscr{F}$ small enough so that $U \subseteq \mathscr{F}^{\prime}$. Thus using (4.7) and (4.9), $E(U)=\sum_{s \in W} E(U: s)=\{0\}$. This shows that for any $\psi \in E\left(\mathscr{F}^{\prime}\right)$ and $\alpha \in C_{c}^{\infty}\left(\mathscr{F}^{\prime}\right)$ with support contained in $U, \psi(H: \alpha)=0$ for all $H \in \mathfrak{t}^{\prime}(\zeta)$. That is, $v_{0}$ is not in the support of the distribution $\psi(H)$ for all $H \in \mathrm{t}^{\prime}(\zeta)$. But $v_{0} \in \mathscr{F}^{\prime}$ was arbitrary so that $\psi(H)=0$ for all $H \in \mathrm{t}^{\prime}(\zeta)$. Thus $E\left(\mathscr{F}^{\prime}\right)$ $=\{0\}$.

That is, for all $\psi \in E(\mathscr{F})$ and $H \in \mathrm{t}^{\prime}(\zeta)$, the support of the distribution $\psi(H)$ is contained in the singular set $\mathscr{F}^{s}=\left\{\nu \in \mathscr{F}: v \notin \mathscr{F}^{\prime}\right\}$ which is a finite union of hyperplanes $V_{\beta}=\{v \in \mathscr{F}:\langle\beta, v\rangle=0\}$ for some $\beta \in \Phi$, $\left.\beta\right|_{a_{1}} \neq 0$. For $U$ an open subset of $\mathscr{F}, V$ a subspace of $\mathscr{F}, s \in W$, and $S$ a subalgebra of $S\left(\mathrm{t}_{\mathbf{c}}\right)$, write $E(U: U \cap V: s: S)=\left\{\psi \in E(U: s: S)\right.$ : for all $H \in \mathrm{t}^{\prime}(\zeta)$, $\operatorname{supp} \psi(H) \subseteq U \cap V\}$. We will also write $E(U: U \cap V)$ for the analogous subset of $E(U)$. We have seen above that $E(\mathscr{F})=E\left(\mathscr{F}: \mathscr{F}^{s}\right)$ $=\sum_{\beta \in \Phi_{1}} E\left(\mathscr{F}: V_{\beta}\right), \Phi_{1}=\left\{\beta \in \Phi:\left.\beta\right|_{a_{1}} \neq 0\right\}$.

We now need to recall a classical theorem about distributions on $\mathbf{R}^{n}$ which are supported on a subspace. Let $U$ be an open subset of $\mathbf{R}^{n}, V$ a subspace with $U \cap V \neq \emptyset$. We identify $V$ with $\mathbf{R}^{k} \times\{0\}$ for some $0 \leq k \leq n$. For $\varphi \in C_{c}^{\infty}(U)$, let $\bar{\varphi} \in C_{c}^{\infty}(U \cap V)$ denote the restriction of $\varphi$ to $U \cap V$. For any distribution $T$ on $U \cap V$ there is a distribution $\bar{T}$ on $U$ given by $\bar{T}(\varphi)=T(\bar{\varphi}), \varphi \in C_{c}^{\infty}(U)$. Clearly if $D$ is any differential operator on $U$ and $T$ is any distribution on $U \cap V$, then $(D \bar{T})(\varphi)$ $=T\left(\overline{D^{*} \varphi}\right)$ gives a distribution on $U$ supported on $U \cap V$. Let $Q$ $=\left\{\left(q_{1}, \ldots, q_{n-k}\right): q_{i} \in \mathbf{N}, 1 \leq i \leq n-k\right\}$. For $q \in Q$ a multi-index, let $D^{q}$ denote the corresponding differential operator on $U$ with respect to the $\mathbf{R}^{n-k}$ variables transverse to $V=\mathbf{R}^{k} \times\{0\}$.

Theorem 4.14 [6]: Let $T$ be a distribution on $U$, supported on $U \cap V$. Then for every $q \in Q$ there is a unique distribution $T_{q}$ on $U \cap V$ so that $T$ $=\sum_{q} D^{q} \bar{T}_{q}$. Further, the sum is locally finite.

Now suppose $U$ is an open subset of $\mathscr{F}, V$ is a subspace of $\mathscr{F}$ which has non-trivial intersection with $U$, and $\psi \in E(U: U \cap V)$. Then using (4.14), for each $H \in \mathrm{t}^{\prime}(\zeta)$ and $q \in Q$ there is a unique distribution $\psi_{q}(H)$ on $U \cap V$ so that $\psi(H)=\sum_{q} D^{q} \overline{\psi_{q}(H)}$. For each $H \in t^{\prime}(\zeta)$, the sum is locally finite. But in fact, using the full strength of (4.5), if $\Omega$ is a relatively compact open subset of $U$, there is an $N \geq 0$ so that for every $H \in \mathrm{t}^{\prime}(\zeta)$ and $\alpha \in C_{c}^{\infty}(\Omega)$,

$$
\begin{equation*}
\psi(H: \alpha)=\sum_{|q| \leq N}(-1)^{|q|} \psi_{q}\left(H: \overline{D^{q} \alpha}\right) \tag{4.15}
\end{equation*}
$$

Further, since for any $\beta \in C_{c}^{\infty}(U \cap V)$ and $q \in Q$ we can find $\alpha \in C_{c}^{\infty}(U)$ with $\overline{D^{q} \alpha}=\beta, \overline{D^{q^{\prime}} \alpha}=0, q^{\prime} \neq q$, it is easy to see that each $\psi_{q}$ must satisfy conditions (4.1), (4.3), (4.4), and (4.5) as a function on $\mathrm{t}^{\prime}(\zeta) \times C_{c}^{\infty}(U \cap V)$.

Lemma 4.16: Suppose $U$ is an open subset of $\mathscr{F}$ and $V$ is a subspace of $\mathscr{F}$ so that $U \cap V \subseteq V^{\prime}$. Then $E(U: U \cap V: s: S(s V))=\{0\}$ for all $s \in W$.

Proof: Suppose $\psi \in E(U: U \cap V: s: S(s V))$. Assume $\psi \neq 0$. We will show this produces a contradiction. Fix $v_{0} \in U \cap V$ such that $v_{0}$ is in the support of $\psi(H)$ for some $H \in \mathrm{t}^{\prime}(\zeta)$. Let $\Omega$ be a relatively compact neighborhood of $v_{0}$ in $U$. For $H \in t^{\prime}(\zeta)$ and $\alpha \in C_{c}^{\infty}(\Omega)$ decompose $\psi(H: \alpha)$ as in (4.15) where $N$ is chosen as small as possible. Then there is a $q \in Q$ so that $|q|=N$ and $\psi_{q}(H)$ is non-trivial on $C_{c}^{\infty}(\Omega \cap V)$ for some $H \in \mathfrak{t}^{\prime}(\zeta)$. Let $s \in W$ and $v \in S(s V)$. For $\beta \in C_{c}^{\infty}(\Omega \cap V)$ choose $\alpha \in C_{c}^{\infty}(\Omega)$ so that $\overline{D^{q} \alpha}$
$=\beta . \overline{D^{q^{\prime}} \alpha}=0, q^{\prime} \neq q$. Then since $\psi \in E(U: s: S(s V))$, for any $v \in S(s V)$,

$$
\begin{aligned}
\psi_{q}(H ; \partial v: \beta)= & (-1)^{|q|} \psi(H: \partial v: \alpha)=(-1)^{|q|} \psi\left(H: p_{s}(v) \alpha\right)= \\
& (-1)^{|q|} \sum_{\left|q^{\prime}\right| \leq N}(-1)^{\left|q^{\prime}\right|} \psi_{q^{\prime}}\left(H: \overline{\left.D^{q^{\prime}}\left(p_{s}(v) \alpha\right)\right)}=\psi_{q}\left(H: p_{s}(v) \beta\right) .\right.
\end{aligned}
$$

Thus the restriction of $\psi_{q}$ to $\mathrm{t}^{\prime}(\zeta) \times C_{c}^{\infty}(\Omega \cap V)$ is an element of $E(\Omega \cap V: s: S(s V))$. Thus $\psi_{q}(H: \beta)=0$ for all $\beta \in C_{c}^{\infty}(\Omega \cap V), H \in t^{\prime}(\zeta)$ by (4.10). This contradicts the assumption that $\psi_{q}$ is non-trivial on $C_{c}^{\infty}(\Omega \cap V)$.

For $V$ a subspace of $\mathscr{F}$, define $\Phi_{V}$ and $V^{\prime}$ as before and let $\mathscr{F}_{V}^{\prime}$ $=\left\{v \in \mathscr{F}:\langle\beta, v\rangle \neq 0\right.$ for $\left.\beta \in \Phi \backslash \Phi_{V}\right\}$. Then $\mathscr{F}_{V}^{\prime}$ is an open subset of $\mathscr{F}$ and $\mathscr{F}_{V}^{\prime} \cap V=V^{\prime}$. When $V=\mathscr{F}, \mathscr{F}_{V}^{\prime}=\mathscr{F}^{\prime}$ and when $V=\{0\}, \mathscr{F}_{V}^{\prime}=\mathscr{F}$.

Theorem 4.17: $E(\mathscr{F})=\{0\}$.
We will show that $E(\mathscr{F})=\{0\}$ by using downward induction on $\operatorname{dim} V$ to prove that $E\left(\mathscr{F}_{V}^{\prime}\right)=\{0\}$ for all $V$. We have already established this for $V=\mathscr{F}$. The statement for $V=\{0\}$ will give the theorem.

Let $V$ be a subspace of $\mathscr{F}$ with $\operatorname{dim} V<\operatorname{dim} \mathscr{F}$. We can assume inductively that for subspaces $V_{1}$ with $\operatorname{dim} V_{1}>\operatorname{dim} V, E\left(\mathscr{F}_{V_{1}}^{\prime}\right)=\{0\}$. Thus $E\left(\mathscr{F}_{V}^{\prime}\right)=E\left(\mathscr{F}_{V}^{\prime}: V^{\prime}\right)$. For $v_{0} \in V^{\prime}$ there is a neighborhood $U$ of $v_{0}$ in $\mathscr{F}_{V}^{\prime}$ so that $E(U: U \cap V)=\sum_{s \in W / W(V)} E(U: U \cap V: s: S(s V))$ by (4.13). But since $U \cap V \subseteq V^{\prime}$, by (4.16), $E(U: U \cap V: s: S(s V))=\{0\}$ for all $s \in W$. Thus $E(U: U \cap V)=E(U)=\{0\} . \quad$ Thus for any $\quad \psi \in E\left(\mathscr{F}_{V}^{\prime}\right), \quad H \in \mathrm{t}^{\prime}(\zeta)$, $v_{0} \notin \operatorname{supp} \psi(H)$. Since this is true for all $v_{0} \in V^{\prime}$ and $\operatorname{supp} \psi(H) \subseteq V^{\prime}, \psi=0$.

## §5. Proof of the main theorem

Let $P=M A_{1} N$ be a cuspidal parabolic subgroup of $G$. For $\omega \in \varepsilon_{2}(M)$ and $v \in \mathscr{F}=\mathfrak{a}_{1}^{*}$, let $\theta_{\omega, v}$ be the character of the corresponding induced representation and let

$$
\varphi_{\alpha}(x)=\int_{\mathscr{F}} \alpha(v) E(P: \psi: v: x) \mu(\omega: v) d v, x \in G
$$

be a wave packet where $\psi$ is a $K_{M^{\prime}}$-finite matrix coefficient for $\omega$ on $M$ and $\alpha \in C_{c}^{\infty}(\mathscr{F})$. Let $W(\omega)=\left\{s \in N_{G}\left(A_{1}\right) / M A_{1}: s \omega=\omega\right\}$.

Let $A$ be a special vector subgroup of $G$ of dimension $p$ and $\mathscr{Y}$ be an $A$-orthogonal set. Let $X \in \mathscr{G}_{A}$ and let $c_{0}(X)$ be its constant term. Let $T$ $=T_{I} T_{R}$ be a $\theta$-stable Cartan subgroup of $G$ which contains $A$ and sat-
isfies $\operatorname{dim} T_{R} \geq \operatorname{dim} A+\operatorname{dim} A_{1}$. Let $\varepsilon\left(T, A, A_{1}\right)$ be 1 if $\operatorname{dim} T_{R}=\operatorname{dim} A$ $+\operatorname{dim} A_{1}$ and be zero otherwise. When $\varepsilon\left(T, A, A_{1}\right)=1$ let $\theta_{\omega, v}^{A}$ be the weighted character defined in (3.3). Let $f=\varphi_{\alpha}, \alpha \in C_{c}^{\infty}(\mathscr{F})$.

Theorem 5.1: For any $h \in T^{\prime}$,

$$
r_{f}(h: \mathscr{Y}: X)=\varepsilon\left(T, A, A_{1}\right) c_{0}(X)(-1)^{p}[W(\omega)]^{-1} \int_{\mathscr{F}}\left\langle\theta_{\omega, v}, f\right\rangle \theta_{\omega, v}^{A}(h) d v .
$$

Proof: For the first part of the proof we will repeat the argument used by Arthur in Theorem 9.1 of [1c].

Suppose $p=0$. Then $\mathscr{G}_{A}=\mathscr{G}$ and for all $X \in \mathscr{G}, r_{f}(h: \mathscr{Y}: X)$ $=c_{0}(X) \int_{T_{R} \mid G} f\left(x^{-1} h x\right) d \dot{x}$ and the result follows by results of HarishChandra in $\S 24$ of [2c] summarized here as (1.3).

Let $p>0$ and assume inductively that the theorem is true for any $\tilde{T}$ and $\tilde{A}$ with $\operatorname{dim} \tilde{A}<p$. Fix $X \in \mathscr{G}_{A}(r), r \geq 0$. If $r>p$ then $D_{X} v(x: \mathscr{G})=0$ and $c_{0}(X)=0$. Thus we can assume inductively that the theorem is true for $X \in \mathscr{G}_{A}\left(r^{\prime}\right), r^{\prime}>r$.

Fix $\zeta \in Z(\mathrm{t})$. For $H \in \mathrm{t}^{\prime}(\zeta), \alpha \in C_{c}^{\infty}(\mathscr{F})$, write

$$
\begin{aligned}
& \psi(H: \alpha)=\tilde{\Delta}(\zeta, H)\left\{r_{\varphi_{\alpha}}(\zeta \exp H: \mathscr{Y}: X)-\right. \\
& \left.\quad c_{0}(X) \varepsilon\left(T, A, A_{1}\right)(-1)^{p}[W(\omega)]^{-1} \int_{\mathscr{F}}\left\langle\theta_{\omega, v}, \varphi_{\alpha}\right\rangle \theta_{\omega, v}^{A}(\zeta \exp H) d v\right\}
\end{aligned}
$$

We must show that $\psi \in E(\mathscr{F})$ so that $\psi(H: \alpha)=0$.
We may as well assume that $T \subseteq L$. Since $p=\operatorname{dim} A>0, T$ is not fundamental. We know that for each $\alpha \in C_{c}^{\infty}(\mathscr{F}), r_{\varphi_{x}}(h: \mathscr{Y}: X)$ and $\theta_{\omega, v}^{A}(h)$ are smooth functions of $h \in T^{\prime}$. Further, for $h=\zeta \exp H \in T^{\prime}$, $h \rightarrow e^{-\rho_{I}(H)} \tilde{\Delta}(\zeta, H)=\prod_{\beta \in \Phi_{I}^{+}}\left(1-\xi_{-\beta}(h)\right) \Delta_{+}(h)$ is a smooth function on $T^{\prime}$. Thus $\psi$ is a function on $\mathrm{t}^{\prime}(\zeta) \times C_{c}^{\infty}(\mathscr{F})$ satisfying (4.1).

Let $z \in \mathscr{Z}$ and let $q=\gamma(z) \in I\left(\mathbf{t}_{\mathbf{c}}\right)$. Then by (3.6), $\tilde{\Phi}_{\omega, v}^{A}(\zeta, H ; \partial q)=q(\lambda$ $+i v) \tilde{\Phi}_{\omega, v}^{A}(\zeta, H)$ where $\lambda \in \mathrm{t}_{M, \mathrm{c}}^{*}$ corresponds to $\omega \in \varepsilon_{2}(M)$. Also $\left\langle\theta_{\omega, v}, z f\right\rangle$ $=q(\lambda+i v)\left\langle\theta_{\omega, v}, f\right\rangle$. Further, because of the induction hypothesis on $r$ and (2.4), $R_{f}(\zeta, H ; \partial q: \mathscr{Y}: X)=R_{z f}(\zeta, H: \mathscr{Y}: X)$ since for all $X_{i} \in \mathscr{G}_{A}(1)$, $X X_{i} \in \mathscr{G}_{A}(r+1)$ so that by the induction hypothesis $R_{f}\left(\zeta, H: \mathscr{Y}: X X_{i}\right)$ $=0$. Now since $f=\varphi_{\alpha}, z f=\varphi_{p(q) \alpha}$ by (2.10). Combining the above observations we see that $\psi$ satisfies (4.2).

Fix $\beta \in \Phi_{R}(\zeta)$. Then

$$
S_{f}^{\beta}(\zeta, H: \mathscr{Y}: X)=R_{f}(\zeta, H: \mathscr{Y}: X)+\tau_{\beta}(H) R_{f}^{T, A_{\beta}}(\zeta, H: \mathscr{Y}: X) .
$$

If $n_{\beta}(A)=0$, then $\tau_{\beta}(H)=0$. If $n_{\beta}(A) \neq 0$, then $\operatorname{dim} A_{\beta}<p$ so by the induction hypothesis the theorem holds for $R_{f}^{T, A_{\beta}}$. But $\operatorname{dim} T_{R} \geq$ $\operatorname{dim} A+\operatorname{dim} A_{1}>\operatorname{dim} A_{\beta}+\operatorname{dim} A_{1}$ so that $\varepsilon\left(T: A_{\beta}: A_{1}\right)=0$. Thus in any case $S_{f}^{\beta}(\zeta, H: \mathscr{Y}: X)=R_{f}(\zeta, H: \mathscr{Y}: X)$, so that using (2.6), for any $H_{0} \in \mathrm{t}_{\beta}^{0}(\zeta), \quad u \in S\left(\mathrm{t}_{\mathbf{c}}\right), \quad R_{f}\left(\zeta, H_{0} ; \partial u: \mathscr{Y}: X\right)^{+}-R_{f}\left(\zeta, H_{0} ; \partial u: \mathscr{Y}: X\right)^{-}=$ $-n_{\beta}(A) \lim _{\theta \rightarrow 0} R_{f}^{T_{\beta}, A_{\beta}}\left(\zeta, H_{0}+\theta\left(X_{\beta}^{\prime}-Y_{\beta}^{\prime}\right) ; \partial\left(\Lambda\left(u-s_{\beta} u\right)\right): \mathscr{Y}_{\beta}: X\right)$ where the limits exist uniformly for $H_{0}$ in compacta of $\mathrm{t}_{\beta}^{0}(\zeta)$. Again, either $n_{\beta}(A)=0$ or else the theorem can be applied to $R_{f}^{T_{\beta}, A_{\beta}}$. Combining this with (3.8) we see that for any $H_{0} \in \mathrm{t}_{\beta}^{0}(\zeta), u \in S\left(\mathrm{t}_{\mathbf{c}}\right), \psi\left(H_{0} ; \partial u: \alpha\right)^{+}=\psi\left(H_{0} ; \partial u: \alpha\right)^{-}$ where the limits exist uniformly on compacta of $\mathrm{t}_{\beta}^{0}(\zeta)$. Thus we see that $\psi$ satisfies (4.3).

Using (2.8) and the fact that $\alpha \rightarrow \varphi_{\alpha}$ is a continuous mapping of $C_{c}^{\infty}(\mathscr{F})$ into $\mathscr{C}(G)$ we see that $R \varphi_{\alpha}$ satisfies the growth condition (4.5). Using (2.11) and (3.5), for any $u \in S\left(\mathrm{t}_{\mathbf{c}}\right), \int_{\mathscr{F}}\left\langle\theta_{\omega, v}, \varphi_{\alpha}\right\rangle \tilde{\Phi}_{\omega, v}^{A}(\zeta, H ; \partial u) d v$ is a finite sum of terms of the form

$$
I(H: \alpha)=c c_{s}(F) c\left(B_{s}: A\right) e^{s \lambda(H)} \int_{\mathscr{F}} \alpha(t v) p_{s}(u: v) e^{i s v(\boldsymbol{H})} d v
$$

where $t \in W(\omega), s \in\left\{w \in W: w A_{1} \subseteq T_{R}\right\}, F$ is the connected component of $\Omega(\zeta)$ containing $H$, and $p_{s}(u)$ is the polynomial on $\mathscr{F}$ given by $p_{s}(u: v)$ $=u(s(\lambda+i v))$. Since $s A_{1} \subseteq T_{R}, s v(H)$ is real for all $H \in \mathfrak{t}$. Further, by (3.7), $c_{s}(F)=0$ unless $\operatorname{Re} s \lambda(H)<0$ for all $H \in \mathscr{F}$. Thus there are a constant $C$ and a continuous seminorm $\mu$ on $C_{c}^{\infty}(\mathscr{F})$ so that

$$
|I(H: \alpha)| \leq C \int_{\mathscr{F}}\left|\alpha(t v) p_{s}(u: v)\right| d v \leq C \mu(\alpha) \text { for all } \alpha \in C_{c}^{\infty}(\mathscr{F})
$$

$H \in \mathfrak{t}^{\prime}(\zeta)$. Thus $\psi$ satisfies (4.5).
To finish the theorem we must know that for every $\alpha \in C_{c}^{\infty}(\mathscr{F})$, $H \rightarrow \psi(H: \alpha)$ extends to a $C^{\infty}$ function on $\Omega_{I}=\mathrm{t}_{I}+\left\{H \in \mathrm{t}_{R}: \beta(H) \neq 0\right.$ for any $\beta \in \Phi$ with $\left.\left.\beta\right|_{t_{R}} \neq 0\right\}$. Note that for $H \in \Omega_{I}$ and $\beta \in \Phi$, if $\xi_{\beta}(\zeta \exp H)$ $=1$, then $\beta \in \Phi_{I}$ and $\beta(H) \in 2 \pi i Z$. Because of (3.5), it is enough to show that $R_{f}, f=\varphi_{\alpha}$, extends smoothly to $\Omega_{I}$. To prove this we need another induction.

Suppose that $T$ is a Cartan subgroup of $G$ with $\operatorname{dim} T_{R}$ maximal. Then every imaginary root of $(\mathrm{g}, \mathrm{t})$ is compact so that, using the remarks following (2.7), $\psi$ extends to a $C^{\infty}$ function about any semi-regular point in $\Omega_{I}$. Since $\psi$ and all its derivatives are bounded in a neighborhood of any singular point of $\Omega_{I}$, it follows from the usual argument that $\psi$ extends to a $C^{\infty}$ function on $\Omega_{I}$. Thus in this case $\psi \in E(\mathscr{F})=\{0\}$ and the theorem is proved.

Assume now that $T$ is a Cartan subgroup of $G$ with $\operatorname{dim} \mathrm{t}_{R}=k$ not maximal, and assume that the theorem is true for Cartan subgroups $\tilde{T}$ of $G$ with $\operatorname{dim} \tilde{\mathrm{f}}_{R}>k$. For all such $\tilde{T}$ with $A \subseteq \tilde{T}_{R}, R_{f}^{\tilde{T}, A}=0$ since $\operatorname{dim} \tilde{T}_{R}>\operatorname{dim} T_{R} \geq \operatorname{dim} A+\operatorname{dim} A_{1}$.

Let $\beta$ be any singular imaginary root of ( $\mathfrak{g}, \mathrm{t}$ ). Then using (2.7), the jump of any derivative of $R_{f}^{T, A}$ across the hyperplane $\beta(H)=0$ is a multiple of $R_{f}^{\tilde{T}, A}$ for a Cartan subgroup $\tilde{T}$ of $G$ with $\operatorname{dim} \tilde{T}_{R}=\operatorname{dim} T_{R}+1$. Thus by the induction hypothesis the jump is zero. The formula for the jump of $R_{f}(\zeta, H: X: \mathscr{Y})$ across a hyperplane of the form $\beta(H)=2 \pi i n$ can also be obtained by (2.7) by using a possibly different $\zeta$, so again we see that $R_{f}$ extends smoothly to a neighborhood of any semi-regular point of $\Omega_{I}$, and hence to $\Omega_{I}$. Thus $\psi$ satisfies (4.4) and is zero.
