## Introduction

In this paper, we classify the irreducible admissible representations of the group $G=G S p(4)$ over a $p$-adic field $F$ of odd residual characteristic by adapting the techniques used for the group $U(2,1)$ in [M1]. The classification is thus based on two concepts: nondegenerate representations and Hecke algebra isomorphisms.

We define a nondegenerate representation as a representation $\sigma$ of a compact open subgroup $L \subset G$ satisfying a certain cuspidality or semisimplicity condition (see Section 1). The importance of these representations for $p$-adic groups is that they play a role analogous to the role of minimal or lowest $K$-types in real Lie groups [V]. In particular, we prove every admissible representation of $G$ contains a nondegenerate representation. Furthermore, we show how they provide a means for partitioning the set of equivalence classes of irreducible admissible representations. Nondegenerate representations thus provide an anchor for investigating the representations of $G$. This is analogous to the role played by minimal $K$-types in real groups.

In real groups, the representations of a reductive group $G$ which contain a given minimal $K$-type $\sigma$ can be classified by relating them to the representations of some smaller reductive group $G^{\prime}$ which contain a minimal $K$-type $\sigma^{\prime}$ derived from $\sigma$. In the $p$-adic case, a similar relation between representations of $G$ containing a nondegenerate representation and representations of some smaller group $G^{\prime}$, is effected by Hecke algebra isomorphisms. As in [HM1, HM2] and [M1], the transfer of representations between $G$ and $G^{\prime}$, arising from the Hecke algebra isomorphisms established here, preserve certain important properties such as temperedness, square integrability and supercuspidality. This is very much in the spirit of cohomological induction results in the case of real groups [V].

As already mentioned, we define the nondegenerate representations in Section 1. A general theory is beginning to emerge for defining these
representations for reductive groups (see [M2], [HM3]), but it is still in a state of flux. As such, we define nondegenerate representations via an exhaustive list. We show, in Section 2, every representation of $G$ contains a nondegenerate representation after tensoring by a one dimensional character of $G$. Section 3 is devoted to a description of the representations of $G$ which contain nondegenerate representations of level one. These representations consist of a cuspidal representation of a parahoric subgroup of $G$. Part two of this paper will give a similar description of the representations of $G$ which contain nondegenerate representations of higher level.

## 1. Nondegenerate representations

Let $F$ be a $p$-adic field of odd residual characteristic and let $R$ denote the ring of integers in $F, \nsim$ the prime ideal in $R$, $\varpi$ a prime element in $\nsim$ and $\mathbb{F}_{q}=R / \nsim$ the residue field with $q$ elements. Let $\mathbf{G}$ be the algebraic group GSp(4). We begin our study of the representations of $G=\mathbf{G}(F)$ by recalling a convenient realization of $G$. Let $F^{4}$ denote the four dimensional space of column vectors. We define a symplectic form $\langle$,$\rangle on F^{4}$. Given $\mathbf{y} \in F^{4}$ (resp. $\left.g \in M_{4}(F)\right)$, let $\mathbf{y}^{t}\left(\right.$ resp. $\left.g^{t}\right)$ be the transpose matrix. For $\mathbf{x}^{t}=\left(x_{1}, x_{2}, x_{3}, x_{4}\right)$ and $\mathbf{y}^{t}=\left(y_{1}, y_{2}, y_{3}, y_{4}\right)$ in $F^{4}$, set

$$
\langle\mathbf{x}, \mathbf{y}\rangle=x_{1} y_{4}+x_{2} y_{3}-x_{3} y_{2}-x_{4} y_{1}
$$

Then

$$
G=\left\{g \in G L\left(F^{4}\right) \mid\langle g \mathbf{v}, g \mathbf{w}\rangle=\mu(g)\langle\mathbf{v}, \mathbf{w}\rangle, \mathbf{v}, \mathbf{w} \in F^{4}\right\}
$$

Here, $\mu(g)$ is a scalar. Let $e_{1}, e_{2}, e_{3}$ and $e_{4}$ denote the standard basis vectors of $F^{4}$, and let $E_{l, l}$ be the $4 \times 4$ matrix whose $(r, s)$ entry is $\delta_{r, l} \delta_{\grave{r}, l}$. Set

$$
H=E_{1,4}+E_{2,3}-E_{3,2}-E_{4,1}
$$

Then $\langle\mathbf{x}, \mathbf{y}\rangle=\mathbf{x}^{t} H \mathbf{y}$ and

$$
G=\left\{g \in G L_{4}(F) \mid g^{\prime} H g=\mu(g) H\right\}
$$

In this setup, the $F$-rational points of the Lie algebra of $\mathbf{G}$ is the set

$$
\mathfrak{g}(F)=\left\{g \in M_{4}(F) \mid g^{\prime} H+H g=\Lambda(g) H\right\}
$$

The Lie algebra $\mathfrak{g}(F)$ is the direct sum of

$$
\begin{aligned}
\Delta \not(4)(F) & =\left\{g \in M_{4}(F) \mid g H+H g^{t}=0\right\} \\
& =\left\{\left[\begin{array}{cccc}
a & M & X & Z \\
m & d & N & X \\
x & n & -d & -M \\
z & x & -m & -a
\end{array}\right]\right\}
\end{aligned}
$$

and the set of scalar matrices.
We now briefly recall some of the structure theory of $G$ with respect to its parahoric subgroups. For a general discussion of such topics, we refer to [BT]. Let $\mathbf{A}$ be the maximal torus in $\mathbf{G}$ consisting of diagonal elements. For $a, b, c \in F^{\times}$let

$$
\begin{equation*}
d(a, b, c)=a E_{1,1}+b E_{2,2}+c E_{3,3}+(b c / a) E_{4,4} \tag{1.1}
\end{equation*}
$$

Then, $A=\mathbf{A}(F)$ is the set of matrices $\{d(a, b, c)\}$. Let $\mathfrak{a}(F)$ be the $F$-rational points of the Lie algebra of A. A basis for the Cartan subalgebra $\mathfrak{a}(F)$ is given by the three vectors

$$
\begin{aligned}
& H_{1}=E_{1,1}-E_{4,4} \\
& H_{2}=E_{2,2}-E_{3,3} \\
& H_{3}=E_{1,1}+E_{2,2}+E_{3,3}+E_{4,4}=\text { identity matrix. }
\end{aligned}
$$

Define two linear functionals $a$ and $b$ on $\mathfrak{a}(F)$ by

$$
\begin{aligned}
& a\left(r H_{1}+s H_{2}+t H_{3}\right)=r-s \\
& b\left(r H_{1}+s H_{2}+t H_{3}\right)=2 s .
\end{aligned}
$$

The set of eight linear functionals

$$
\Phi=\{ \pm a, \pm b, \pm(a+b), \pm(2 a+b)\}
$$

form a root system of type $C_{2}$. The Borel subgroup B of upper triangular matrices in $\mathbf{G}$ determines an ordering of the roots in which $a$ and $b$ are the
simple roots. Set

$$
\begin{align*}
& E_{M}=E_{a}=E_{1,2}-E_{3,4}  \tag{1.2}\\
& E_{N}=E_{b}=E_{2,3} \\
& E_{X}=E_{\mathrm{a}+b}=E_{1,3}+E_{2,4} \\
& E_{Z}=E_{2 a+b}=E_{1,4} \\
& E_{m}=E_{-a}=E_{2,1}-E_{4,3} \\
& E_{n}=E_{-b}=E_{3,2} \\
& E_{\mathrm{r}}=E_{-a-b}=E_{3,1}+E_{4,2} \\
& E_{z}=E_{-2 a-b}=E_{4,1} .
\end{align*}
$$

These vectors are root vectors, i.e.

$$
\left[H, E_{\imath}\right]=c(H) E_{\imath} \text { for } c \text { a root and } H \in \mathfrak{a}(F) .
$$

The one-dimensional root space $u_{c}(F)=F E_{\imath}$ of $\mathfrak{g}(F)$ can be exponentiated into root groups $U_{c}$ inside $G$. Denote by $\mathbf{U}_{\iota}$ the corresponding algebraic subgroup of $\mathbf{G}$ so that $U_{c}=\mathbf{U}_{c}(F)$. The exponential map

$$
\begin{equation*}
u_{c}: u_{c}(F) \rightarrow U_{c} \tag{1.3}
\end{equation*}
$$

is given by $u_{t}\left(x E_{c}\right)=1+x E_{c}$. Abbreviate $u_{c}\left(x E_{c}\right)$ to $u_{t}(x)$. The $F$-rational points of $\mathbf{B}$ is equal to the subgroup of $G$ generated by $A$ and $U_{c}(c>0)$. We write this as

$$
\mathbf{B}(F)=A \prod_{c>0} U_{c} .
$$

For $i$ an integer, let

$$
\begin{align*}
U_{c, i} & =u_{c}\left(\not \mu^{i}\right), \quad c \in \Phi \\
U_{0, i} & =\left\{d(a, b, c) \mid a, b, c \equiv 1 \bmod \not \mu^{i}\right\}, \quad i \geqslant 0 . \tag{1.4}
\end{align*}
$$

The subgroup of $G$ generated by $\mathbf{A}(R), U_{\iota, 0}(c>0)$ and $U_{c, 1}(c<0)$, which we write as

$$
B=\mathbf{A}(R) \prod_{c>0} U_{c, 0} \prod_{c<0} U_{c, 1},
$$

is an Iwahori subgroup of $G$. It consists of those elements of $K=\mathbf{G}(R)$ which are upper triangular $\bmod \mu$.

Let

$$
\begin{equation*}
\mathbf{N}=\text { normalizer of } \mathbf{A} \text { in } \mathbf{G} \tag{1.5}
\end{equation*}
$$

The group $N=\mathbf{N}(F)$ is the normalizer of $A$ in $G$. For $c$ a root, set

$$
w_{c}(t)=u_{c}(t) u_{-c}\left(-t^{-1}\right) u_{c}(t), \quad t \in F^{\times} .
$$

The $w_{c}(t)$ 's and $A$ generate $N$. The Weyl group is of course defined to be $W=N / A$. It is generated by the images in $W$ of the two elements

$$
\begin{align*}
& s_{0}=E_{1,1}+E_{2,3}-E_{3,2}+E_{4,4}=w_{b}(1) \text { and } \\
& s_{1}=E_{1,2}+E_{2,1}+E_{3,4}+E_{4,3}=w_{a}(1) d(1,-1,1) \tag{1.6}
\end{align*}
$$

If $I$ is a subset of $\left\{s_{0}, s_{1}\right\}$, the standard parabolic subgroup $P(I)$ is the subgroup of $G$ generated by $\mathbf{B}(F)$ and $I$. Denote by $\mathbf{P}_{I}$, the parabolic subgroup of $\mathbf{G}$ such that $\mathbf{P}_{I}(F)=P(I)$. The algebraic group $\mathbf{P}_{I}$ has a Levi decomposition

$$
\begin{equation*}
\mathbf{P}_{I}=\mathbf{M}_{l} \mathbf{U}_{I} . \tag{1.7}
\end{equation*}
$$

The group $\mathbf{M}_{I}$ may be chosen so that $\mathbf{M}_{I}(F)$ is the subgroup of $G$ generated by $A, I$ and

$$
\left\{U_{c} \mid c \text { a linear combination of elements in } I\right\} .
$$

Here, we have of course identified $s_{0}$ with $b$ and $s_{1}$ with $a$. The group $\mathbf{M}_{I}(F)$ is invariant under the Cartan involution of inverse transpose.

The affine Weyl group is defined to be the group

$$
\begin{equation*}
W^{\mathrm{aff}}=N / \mathbf{A}(R) \tag{1.8}
\end{equation*}
$$

It is generated by the images in $W^{\text {aff }}$ of $s_{0}, s_{1}$ and the two elements

$$
\begin{equation*}
s_{2}=-\varpi^{-1} E_{1,4}+E_{2,2}+E_{3,3}+\varpi E_{4,1}=w_{-2 a-b}(\varpi) \tag{1.9}
\end{equation*}
$$

and

$$
t=E_{1,3}+E_{2,4}+\varpi E_{3,1}+\varpi E_{4,2}
$$

## Let

$$
\begin{equation*}
S=\left\{s_{0}, s_{1}, s_{2}\right\} \tag{1.10}
\end{equation*}
$$

The element $t$ normalizes the Iwahori subgroup $B$. We also have $t s_{1}=s_{1} t$ and $s_{0} t=t s_{2}$. The Dynkin diagrams for $W$ and $W^{\text {aff }}$ are

$$
\begin{aligned}
& o_{s_{0}}=o_{s_{1}} \text { for } W \\
& o_{s_{0}}=o_{s_{1}}=o_{s_{2}} \text { for } W^{\text {aff }}
\end{aligned}
$$

If $I$ is a subset of $S$, the standard parahoric subgroup $P_{I}$ is the subgroup of $G$ generated by $B$ and I. A parahoric subgroup is a $G$-conjugate of a standard parahoric subgroup. The parahoric subgroup $P_{I}$ generated by $B$ and $I$ is compact if and only if $I$ is a proper subset of $S$. In particular, there are seven standard compact parahoric subgroups. They are

$$
\begin{aligned}
& K=P_{\left\{s_{0}, s_{1}\right\}}=\mathbf{G}(R)\left(\text { conjugate to } P_{\left\{s_{2}, s_{1}\right\}}\right) \\
& J=P_{\left\{s_{0}, s_{2}\right\}} \\
& \left.P_{\left\{s_{0}\right\}} \text { (conjugate to } P_{\left\{s_{2}\right\}}\right) \\
& P_{\left\{s_{1}\right\}} \\
& B=P_{\varnothing}
\end{aligned}
$$

The two groups $K=P_{\left\{s_{0}, s_{1}\right\}}=\mathbf{G}(R)$ and $J=P_{\left\{s_{0}, s_{2}\right\}}$ are representatives for the two conjugacy classes of maximal compact subgroups of $G$.

Given a parahoric subgroup $P$, let $P_{1}$ be the maximal normal pro-psubgroup of $P$. To describe $P_{1}$, and more generally a filtration of $P$ which we use in Sections 4 and 5, we review the litany of affine roots and heights.

Let $\mathbf{X}$ be the $\mathbb{Z}$-span of the simple roots $a$ and $b$. An affine root is an element $\beta=(c, n)$ in the additive group $\mathbf{X} \times \mathbb{Z}$ subject to the condition that $c \in(\Phi \cup\{0\})$ and $n \in \mathbb{Z}$. If $n \geqslant 0$, set $U_{\beta}=U_{c, n}$. Each affine root $\beta$ has a unique decomposition

$$
\beta=h_{0}(\beta)(b, 0)+h_{1}(\beta)(a, 0)+h_{2}(\beta)(-2 a-b, 1) .
$$

Thus, for example, we have $(0,1)=1(b, 0)+2(a, 0)+1(-2 a-b, 1)$. For $I \subset S$, define a height function $h t_{l}$ on the affine roots by the sum

$$
h t_{l}(\beta)=\sum^{\prime} h_{l}(\beta)
$$

over those $i$ for which $s_{t} \notin I$. Then,

$$
\begin{equation*}
P_{I, 1}=\text { subgroup of } G \text { generated by } U_{\beta} \text { such that } h t_{l}(t) \geqslant 1 \tag{1.12}
\end{equation*}
$$

More generally, if $t \in \mathbb{N}$, set

$$
\begin{equation*}
P_{I, t}=\text { subgroup of } G \text { generated by } U_{\beta} \text { such that } h t_{l}(t) \geqslant t . \tag{1.13}
\end{equation*}
$$

The $P_{I, I}$ 's are a filtration of normal subgroups in $P_{I}$. When $I=\left\{s_{0}, s_{1}\right\}$, so that $P_{I}=K=\mathbf{G}(R)$, the group $P_{I, t}$ is the $t$-th principal congruence subgroup of $K$. We defer a more general discussion of the groups $P_{I, t}$ until Sections 4 and 5 .

The quotient group $K / K_{1}$ is of course isomorphic to $\mathbf{G}\left(\mathbb{F}_{q}\right)$. For $I \subset\left\{s_{0}, s_{1}\right\}$, the group $P_{I} / P_{I, 1}$ is $\mathbf{M}_{I}\left(\mathbb{F}_{q}\right)$. To identify $J / J_{1}$, let $\mathbf{G}(\mathbf{S p ( 2 )} \times \mathbf{S p ( 2 ) )}$ be the algebraic subgroup of $\mathbf{G}$ consisting of those elements whose $(1,2),(1,3)$, $(2,1),(2,4),(3,1),(3,4),(4,2)$ and $(4,3)$ entries are zero. For $a \in R$, let a be the image of $a$ in $\mathbb{F}_{q}$. The group $J / J_{1}$ can be identified with the $\mathbb{F}_{q}$-rational points of $\mathbf{G}(\mathbf{S p ( 2 )} \times \mathbf{S p ( 2 ) )}$ via the map

$$
\left[\begin{array}{cccc}
a & b & c & d \varpi^{-1}  \tag{1.14}\\
e \varpi & f & g & h \\
i \varpi & j & k & m \\
n \varpi & r \varpi & s \varpi & t
\end{array}\right] \bmod J_{1} \rightarrow\left[\begin{array}{cccc}
\mathbf{a} & \mathbf{0} & \mathbf{0} & \mathbf{d} \\
\mathbf{0} & \mathbf{f} & \mathbf{g} & \mathbf{0} \\
\mathbf{0} & \mathbf{j} & \mathbf{k} & \mathbf{0} \\
\mathbf{n} & \mathbf{0} & \mathbf{0} & \mathbf{t}
\end{array}\right] .
$$

The group $\mathbf{G}(\mathbf{S p}(\mathbf{2}) \times \mathbf{S p}(\mathbf{2}))\left(\mathbb{F}_{q}\right)$ is isomorphic to the group

$$
\left\{\left(g_{1}, g_{2}\right) \in \mathbf{G} \mathbf{L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) \times \mathbf{G} \mathbf{L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) \mid \operatorname{det} g_{1}=\operatorname{det} g_{2}\right\} .
$$

The isomorphism is given by the map

$$
\left[\begin{array}{cccc}
a & 0 & 0 & d  \tag{1.15}\\
0 & f & g & 0 \\
0 & j & k & 0 \\
n & 0 & 0 & t
\end{array}\right] \rightarrow\left[\begin{array}{cc}
a & d \\
n & t
\end{array}\right]\left[\begin{array}{cc}
f & g \\
j & k
\end{array}\right]
$$

In all cases, the group $P_{I} / P_{I, 1}$ can be identified with the $\mathbb{F}_{q}$-rational points of a reductive group with Dynkin diagram I.

A cuspidal representation of a standard compact parahoric subgroup $P$ is a cuspidal representation of $P / P_{1}$ inflated to $P$. We have developed enough notation to make the following definition.

Definition 1.1. A nondegenerate representation of level one in standard position is a pair $(P, \sigma)$ consisting of a standard compact parahoric subgroup $P$ and an irreducible cuspidal representation $\sigma$ of $P$.

Our next goal is to define the nondegenerate representations of unramified and ramified type. To accomplish this we first establish more notation and conventions. Let $\tilde{G}$ denote the group $G L_{4}(F), \widetilde{K}$ denote $G L_{4}(R)$ and $\widetilde{K}_{l}$ the $i$ th principal congruence subgroup of $\tilde{K}$. If $\tilde{L}$ is a subgroup of $\tilde{G}$, let $L$ denote the intersection of $\tilde{L}$ with $G$. This is consistent with our previous use of $K$ as $\mathbf{G}(R)$. Let $\tilde{\mathfrak{g}}=M_{4}(F)$ (resp. $\tilde{\mathfrak{g}}(R)=M_{4}(R)$ ) be the $F$-rational (resp. $R$-rational) points of the Lie algebra of $\mathbf{G L}_{4}$. Let $\mathfrak{g}$ (resp. $\mathfrak{g}(R)$ ) be the analogous sets for the Lie algebra of G. Define a form on $\tilde{\mathfrak{g}}$ by

$$
\begin{equation*}
\langle x, y\rangle=\operatorname{tr}_{\tilde{\mathfrak{g}}}(x y) \tag{1.16}
\end{equation*}
$$

The restriction of $\langle$,$\rangle to \mathfrak{g}$ is nondegenerate. A lattice I is an open compact $R$-submodule in $\tilde{\mathfrak{g}}$ or $\mathfrak{g}$. If $\mathfrak{I} \subset \tilde{\mathfrak{g}}$, define the dual lattice $\mathfrak{I}^{*}$ in $\tilde{\mathfrak{g}}$ by

$$
\begin{equation*}
\mathfrak{I}^{*}=\{x \in \tilde{\mathfrak{g}} \mid\langle x, \mathfrak{l}\rangle \subset R\} . \tag{1.17}
\end{equation*}
$$

If $\mathfrak{I} \subset \mathfrak{g}$, the dual lattice $I^{*}$ in $\mathfrak{g}$ is defined by the obvious modification of (1.17), i.e., $\tilde{\mathfrak{g}}$ is replaced by $\mathfrak{g}$. The lattices $\tilde{\mathfrak{g}}(R)$ and $\mathfrak{g}(R)$ are self-dual in $\tilde{\mathfrak{g}}$ and $\mathfrak{g}$ respectively. If $\mathfrak{h}$ is a subalgebra of $\mathfrak{g}$ let $\mathfrak{h}^{\perp}($ resp. $\mathfrak{h}$ \#) be the orthogonal complement of $\mathfrak{b}$ in $\mathfrak{g}$ (resp. $\tilde{\mathfrak{g}}$ ). We have

$$
\begin{equation*}
\mathfrak{h}^{\#}=\mathfrak{h}^{\perp} \oplus \mathfrak{g}^{\#} \tag{1.18}
\end{equation*}
$$

Let $i \geqslant j$ be positive integers. The Cayley transform

$$
\begin{equation*}
c(x)=(1-x)(1+x)^{-1} \tag{1.19}
\end{equation*}
$$

maps $\varpi^{\prime} \tilde{\mathfrak{g}}(R)$ and $\varpi^{\prime} \mathfrak{g}(R)$ bijectively to $\tilde{K}_{l}$ and $K_{l}$ respectively. Taking quotients, the Cayley transform becomes an isomorphism

$$
\begin{aligned}
& \varpi^{\prime} \tilde{\mathfrak{g}}(R) / \varpi^{i+\prime} \tilde{\mathfrak{g}}(R) \rightarrow \tilde{K}_{i} / \tilde{K}_{t+\prime} \\
& \varpi^{\prime} \mathfrak{g}(R) / \varpi^{i+\prime} \mathfrak{g}(R) \rightarrow K_{t} / K_{t+\prime}
\end{aligned}
$$

We use this isomorphism to identify the quotient groups. Let $\mathfrak{g}^{\#}(R)=$ $\mathfrak{g}^{\#} \cap \tilde{\mathfrak{g}}(R)$. We have

$$
\begin{equation*}
\tilde{K}_{t} / \tilde{K}_{i+j}=K_{t} / K_{i+\prime} \oplus \varpi^{\prime} \mathfrak{g}^{\#}(R) / \varpi^{i+\prime} \mathfrak{g}^{\#}(R) \tag{1.20}
\end{equation*}
$$

In this setting, the characters of $K_{t} / K_{t+}$ can be viewed as the characters of $\widetilde{K}_{l} / \widetilde{K}_{l+}$ trivial on $\varpi^{\prime} \mathrm{g}^{\#}(R) / \varpi^{\prime+} \mathrm{g}^{\#}(R)$. We need to describe a very important realization of these characters. Let $\psi$ be an additive character of $F$ with conductor $R$. We identify the character group $\left\{\tilde{K}_{t} / \tilde{K}_{i+1}\right\}^{\wedge}$ with $\varpi^{-(t+1)} \tilde{\mathfrak{g}}(R) /$ $\varpi^{-\prime} \tilde{\mathfrak{g}}(R)$ via the map $\left(\alpha+\varpi^{-\prime} \tilde{\mathfrak{g}}(R)\right) \rightarrow \Omega_{\alpha}$,

$$
\begin{equation*}
\Omega_{\alpha}(c(x))=\psi(\langle x,-\alpha\rangle / 2), \quad x \in \varpi^{\prime} \tilde{\mathfrak{g}}(R) \tag{1.21}
\end{equation*}
$$

If $c(x)$ is written in the form $1+y$ with $y$ in $\varpi^{\prime} \tilde{\mathfrak{g}}(R)$, then $\Omega_{\alpha}(c(x))=$ $\psi(\langle x, \alpha\rangle)$. The character group $\left\{K_{l} / K_{t+l}\right\}^{\wedge}$ is identified with the group $\varpi^{-(t+1)} \mathfrak{g}(R) / \varpi^{-t} \mathfrak{g}(R)$.

Assume $j=1$. Take $\Omega_{\alpha}$ of the form (1.21), with $\alpha \in \mathfrak{g}$. Multiplication by $\varpi^{(i+1)}$ allows us to identify $\varpi^{-(t+1)} \mathfrak{g}(R) / \varpi^{-l} \mathfrak{g}(R)$ with $\mathfrak{g}\left(\mathbb{F}_{q}\right)$, so we can view $\varpi^{(t+1)} \alpha \bmod \mu$ as an element in $\mathfrak{g}\left(\mathbb{F}_{q}\right)$. Decompose this element into its semisimple and nilpotent parts

$$
\begin{equation*}
\varpi^{(i+1)} \alpha \bmod \neq \mathbf{s}+\mathbf{n} \tag{1.22}
\end{equation*}
$$

When $\mathbf{s}$ is not a scalar matrix we shall soon define a group $L$ and a representation $\Omega_{\mathrm{s}}$ of $L$. The collection of the ( $L, \Omega_{\mathrm{s}}$ )'s and their $G$-conjugates shall be the nondegenerate representations of unramified type.

In order to define the groups $L$, we recall the standard parabolic subgroups of $G$. Given a subset $I \subset\{a, b\}$, let $\mathbf{P}_{I}=\mathbf{M}_{I} \mathbf{U}_{I}$ be the Levi decomposition (1.7). Let $m_{l}\left(\mathbb{F}_{q}\right), \mathfrak{u}_{I}\left(\mathbb{F}_{q}\right)$ and $\mathfrak{p}_{I}\left(\mathbb{F}_{q}\right)$ be the $\mathbb{F}_{q}$-rational points of the Lie algebra of $\mathbf{M}_{I}, \mathbf{U}_{I}$ and $\mathbf{P}_{I}$ respectively.

Consider (1.22). Let $\alpha^{\prime}$ be a $K$-conjugate of $\varpi^{(t+1)} \alpha \bmod ~ p$ so that,

$$
\begin{equation*}
\alpha^{\prime} \in \mathfrak{p}_{I}\left(\mathbb{F}_{q}\right), \quad \text { but } \quad \alpha^{\prime} \notin \mathfrak{p}_{I^{\prime}}\left(\mathbb{F}_{q}\right) \tag{1.23}
\end{equation*}
$$

for all proper subsets $I^{\prime}$ of $I$. Let $\alpha^{\prime}=\mathbf{s}^{\prime}+\mathbf{n}^{\prime}$ be the Jordan decomposition. The semisimple part $\mathbf{s}^{\prime}$ lies in $\mathfrak{m}_{I}\left(\mathbb{F}_{q}\right)$, while the nilpotent part $\mathbf{n}^{\prime}$ lies in $\mathfrak{u}_{I}\left(\mathbb{F}_{q}\right)$. Let $\underline{\mathbf{U}}_{I}$ be the unipotent subgroup opposite to $\mathbf{U}_{I}$, i.e., if $\theta$ is the Cartan involution of inverse transpose, then $\underline{\mathbf{U}}_{I}=\theta\left(\mathbf{U}_{I}\right)$. For $m \in \mathbb{N}$, let $M_{I, m}$, $U_{I, m}$ and $\underline{U}_{I, m}$ be the intersections of $K_{m}$ with $\mathbf{M}_{I}(F), \mathbf{U}_{I}(F)$ and $\underline{\mathbf{U}}_{I}(F)$ respectively.

We now define the nondegenerate representations of unramified type. Let $L$ be the group

$$
\begin{equation*}
L=\underline{U}_{l, l+1} M_{l, t} U_{l, l} . \tag{1.24}
\end{equation*}
$$

The group $L$ is in fact a filtration subgroup (1.15) of the parahoric subgroup $P_{I}$. The restrictions of $\Omega_{\alpha^{\prime}}$ and $\Omega_{\mathrm{s}^{\prime}}$ to $L$ are equal. Denote this character by $\Omega_{s^{\prime}}$.

Definition 1.2. A nondegenerate representation of unramified type in standard position is a pair $\left(L, \Omega_{\mathrm{s}^{\prime}}\right)$ as in $(1.23,24)$.

We proceed to define the nondegenerate representations of ramified type. The basic scheme of things here parallel the unramified case. We construct a subgroup $L$ related to $K_{t}$ and a character $\Omega$ of $L$ satisfying certain properties. The kernel of $\Omega$ shall contain $K_{i+1}$ and the restriction of $\Omega$ to $K_{l}$ will be represented by a nilpotent element of $\mathfrak{g}\left(\mathbb{F}_{q}\right)$.

Let $i \in \mathbb{N}$. Consider the five classes of sets $\tilde{\alpha}$ described in (1.25). Here, $u$, $v, \varepsilon \in R^{\times}, \varepsilon$ a nonsquare, and $a, b, c, d, e, f \in R$. In (1.25b), $a^{2}-b c$, $d^{2}-e f \in R^{\times}$.

$$

\end{array}\right]\right\}(i \geqslant 2) . \tag{1.25e}
\end{align*}
$$

We have written each of the five sets in (1.25a-e) in the form

$$
\begin{equation*}
\varpi^{-1-1} \alpha+\tilde{I} \tag{1.26}
\end{equation*}
$$

where $\alpha \in \mathfrak{g}$, and $\tilde{I}$ is a matrix of ideals. The convention for this notation is that $\tilde{\mathbb{l}}$ is the set of elements in $\tilde{\mathfrak{g}}(R)$ with the entries in the indicated ideals. Thus, in $(1.25 \mathrm{a})$, elements of $\tilde{I}$ have their $(1,1)$ entry in $\varpi^{-l-1} \nprec$, their $(1,4)$ entry in $\varpi^{-1-1} R$, their $(4,1)$ entry in $\varpi^{-l-1} \ell^{2}$ and so forth. We shall use similar notation later to describe other sets of matrices.

Note that $\tilde{I}$ is an $R$-submodule of $\tilde{\mathfrak{g}}$. Let $\tilde{I}^{*}$ be the dual lattice (c.f. (1.17)). For each $\tilde{\alpha}$ as in (1.25), let $\tilde{L}$ be the group

$$
\tilde{L}=1+\tilde{I}^{*}=\left\{1+x \mid x \in \tilde{I}^{*}\right)
$$

Let $\alpha, I$ and $I^{*}$ denote the intersection of $\tilde{\alpha}, \tilde{I}$ and $\tilde{I}^{*}$ respectively with $\mathfrak{g}$. Note that $\mathfrak{I}^{*}$ is also the dual lattice of I in $\mathfrak{g}$. Let $L$ be the intersection of $\tilde{L}$ with $G$. It is easy to check that

$$
\tilde{L}=c\left(\tilde{I}^{*}\right) \quad \text { and } \quad L=c\left(\mathrm{I}^{*}\right)
$$

The group $L$ is a filtration subgroup (1.15) of some parahoric subgroup $P_{I}$. Define a character $\Omega_{\alpha}$ on $\tilde{L}$, hence $L$, in analogy with (1.21) by the formula

$$
\Omega_{\alpha}(c(x))=\psi(\langle x,-\alpha\rangle / 2), \quad x \in \tilde{I}
$$

The group $L$ contains $K_{i+1}$ and the restriction of $\Omega_{\alpha}$ to $K_{t+1}$ is trivial. In cases ( $1.25 \mathrm{~b}, \mathrm{c}, \mathrm{d}, \mathrm{e}$ ), the group $L$ contains $K_{\text {, }}$ and the restriction of $\Omega_{\alpha}$ to $K_{i}$ is represented in $\mathfrak{g}\left(\mathbb{F}_{q}\right)$ by reducing elements in $\varpi^{+1} \alpha \bmod h$. In case (1.25b) (resp. $(1.25 \mathrm{c}, \mathrm{d}, \mathrm{e})$ ), $\varpi^{\prime+1} \alpha \bmod \nsim$ is equal to $a E_{1,3}+b E_{1,4}+c E_{2,3}+a E_{2,4}$ (resp. $E_{1,4}$ ) mod $\nless$. In case (1.25a), the group $L$ does not contain $K_{l}$, but the restriction of $\Omega_{\alpha}$ to the intersection $L \cap K_{l}$ can be extended to $K_{i}$. The extensions of $\Omega_{\alpha}$ to $K_{t}$ will be represented in $\mathfrak{g}\left(\mathbb{F}_{q}\right)$ by elements of the form

$$
E_{1,2}+E_{2,3}-E_{3,1}+a E_{1,3}+a E_{2,4}+b E_{1,4} \bmod \nsim .
$$

These elements are $K$-conjugate to $\varpi^{t+1} \alpha$ mod $\nprec$. In every case, the extension of $\Omega_{\alpha}$ to $K_{l}$ is represented by a nilpotent element $\mathbf{n}$.

Definition 1.3. A nondegenerate representation of ramified type in standard position is a pair $\left(L, \Omega_{\alpha}\right)$, with $\tilde{\alpha}$ of the form (1.25).

## 2. Nondegenerate representations as lowest $K$-types

Consider an admissible irreducible representation $(\pi, V)$ of $G$. In this section we show some twist $\pi \otimes \chi, \chi$ a one-dimensional representation of $G$, must contain a standard minimal nondegenerate representation $(L, \sigma)$. The approach taken here is the same as the one used in [M1] for $U(2,1)$.

Given an irreducible admissible representation $(\pi, V)$, define the level of $\pi$ to be the minimum $i$ such that $V^{K_{1}}$, the space of vectors in $V$ fixed by $K_{l}$, is nonzero. The representation $\pi$ is said to have minimal level under twisting if the level of $\pi$ is less than or equal to the level of all twists $\pi \otimes \chi$. It is clear we can assume $\pi$ has minimal level under twisting. Let $i+1$ be the minimal level. Choose a nonzero vector $v$ fixed by $K_{i+1}$ and let $K_{l} v$ be the span of $K_{l}$ transforms of $v$. This finite dimensional space can be decomposed into irreducible $K_{t} / K_{t+1}$ subspaces. If we select a vector from an irreducible component of $K_{i} v$ and replace $v$ by this vector, we can assume $K_{l} v$ is an irreducible $K_{t} / K_{t+1}$ space. If $i=0$, then $\pi$ restricted to $K$ contains a representation $\sigma$ of $K / K_{1}=\mathbf{G}\left(\mathbb{F}_{q}\right)$. By Harish-Chandra's philosophy of cusp forms [HC], there is a parahoric subgroup $P \subset K$ as well as a cuspidal representation $\Omega$ of $P$ such that the restriction of $\sigma$ to $P$ contains $\Omega$. In particular, $\pi$ must contain a nondegenerate representation.

Suppose $i \geqslant 1$. As in Section 1, we identify the characters of $K_{t} / K_{t+1}$ with $\mathrm{g}\left(\mathbb{F}_{q}\right)$. The group $K_{l} / K_{t+1}$ acts on $K_{l} v$ by a character $\Omega_{\alpha}$. For $k \in K$, it is clear that $\pi(k)\left(K_{l} v\right)$ is also an irreducible $K_{l} / K_{i+1}$ subspace. Indeed, if we set $\alpha^{\prime}=k \alpha k^{-1}$, then the group $K_{i} / K_{l+1}$ acts on $\pi(k)\left(K_{l} v\right)$ by the character $\Omega_{\alpha^{\prime}}$. By taking an appropriate $k$, we can assume $\alpha^{\prime}$ satisfies (1.23). Let $L$ be the group (1.24), and let $\Omega_{\mathbf{s}^{\prime}}$ be the restriction of $\Omega_{\alpha}$ to $L$. If $\mathbf{s}^{\prime}$ is not a scalar, the pair ( $L, \Omega_{\mathrm{s}^{\prime}}$ ) is by definition a minimal nondegenerate representation of unramified type. Assume $\mathbf{s}^{\prime}$ is a scalar. Then, it is easily seen that there is a one-dimensional character $\chi$ of $G$ trivial on $K_{t+1}$, and represented by $-\mathbf{s}^{\prime}$ on $K_{l} / K_{l+1}$. The representation $\pi \otimes \chi$ still have level $i+1$. Furthermore, the $\pi \otimes \chi$ action of $K_{l} / K_{t+1}$ on $K_{l} v$ is a character $\Omega_{\mathrm{n}}, \mathbf{n}$ an upper triangular nilpotent element of $\mathfrak{g}\left(\mathbb{F}_{q}\right)$. Consider the three cases delineated by the rank of $\mathbf{n}$. In the following analysis, we define two groups $L_{+}$and $L$. The two groups will change during the course of the analysis, but $L_{+}$will always be normal in $L$ and the quotient will always be abelian.

Case 1: $\operatorname{rank}(\mathbf{n})=3$. We can take $\mathbf{n}$ of the form

$$
\mathbf{n}=E_{a}+E_{b} \bmod \mu
$$

In the notation of (1.11) and (1.13), it is easily verified that

$$
\begin{equation*}
L_{+}=B_{4 i} \tag{2.1a}
\end{equation*}
$$

is contained in the kernel of $\Omega_{n}$. Let

$$
\begin{equation*}
L=B_{4 i-1} . \tag{2.1b}
\end{equation*}
$$

The characters of $L / L_{+}$can be realized as in (1.21) by the cosets

$$
\varpi^{-t-1}\left\{\left[\begin{array}{cccc}
0 & a & 0 & 0  \tag{2.2}\\
0 & 0 & b & 0 \\
0 & 0 & 0 & -a \\
c \varpi & 0 & 0 & 0
\end{array}\right]+\left[\begin{array}{cccc}
\not & \mu & R & R \\
h & h & h & R \\
h & h & \mu & \mu \\
\mu^{2} & h & p & \mu
\end{array}\right]\right\}
$$

$a, b, c \in R$. Let $v \neq 0$ be a vector in $V$ fixed by $L_{+}$. Write $L v$ for the span of the $L$ transforms of $v$. The decomposition of $L v$ into $L$ subspaces yields characters with $a=b=1$. If $c \neq 0 \bmod h$, the representation $\Omega$ of $L$ on $L v$ is nondegenerate of type (1.25a). On the other hand, if $c=0 \bmod \nprec$, the vector $w=\pi(t) v$ transforms under $L$ as a character with $b=0$. The
decomposition of $K_{l} w$ into $K_{t} / K_{t+1}$ subspaces give vectors which transform under $K_{t} / K_{i+1}$ by characters $\Omega_{\mathrm{n}}, \mathbf{n} \in \mathfrak{g}\left(\mathbb{F}_{q}\right)$ nilpotent of rank 2 .

Case 2: $\operatorname{rank}(\mathbf{n})=2$. We can assume $\mathbf{n}$ has the form

$$
\mathbf{n}=A E_{a+b}+B E_{2 a+b}+C E_{b} \bmod \not \mu, \quad \text { with } A^{2}-B C \neq 0 \bmod \not \mu
$$

The kernel of $\Omega_{n}$ contains the group

$$
\begin{equation*}
L_{+}=P_{\left\{\left\{_{1}\right\}, 2 t\right.} \tag{2.3a}
\end{equation*}
$$

Take $v \neq 0$ fixed by $L_{+}$. Set

$$
\begin{equation*}
L=P_{\left\{s_{1}\right\}, 2 t-1} \tag{2.3b}
\end{equation*}
$$

Realize the character group $\left\{L / L_{+}\right\}^{\wedge}$ as the cosets
$x, y, z, d, e, f \in R$. Decompose $L v$, as in the rank three case, into irreducible $L / L_{+}$subspaces and choose a nonzero vector, again relabeled $v$, which transforms by a character with $x=A, y=B$ and $z=C$. If $d^{2}-e f \neq$ $0 \bmod \mu$, the representation $\Omega$ of $L$ on $L v$ is nondegenerate of type (1.25b). The alternative is $d^{2}-e f=0 \bmod \not \kappa$. Both $L$ and $L_{+}$are normalized by the element $t$ in (1.0). Consequently, $L$ acts on the vector $w=\pi(t) v$ according to the character

In turn, $K_{l} / K_{t+1}$ acts on $w$ as a character $\Omega_{\mathbf{n}^{\prime}}$, with $\mathbf{n}^{\prime} \in \mathfrak{g}\left(\mathbb{F}_{q}\right)$ a nilpotent element of rank 1 or 0 . If $\mathbf{n}^{\prime}$ is of rank 0 then $(\pi, V)$ possesses a nonzero $K_{\text {}}$-fixed vector contradicting the hypothesis of minimal level $i+1$. We therefore can assume $\mathbf{n}^{\prime}$ has rank 1 .

Case 3: $\operatorname{rank}(\mathbf{n})=1$. Here, we write $\mathbf{n}$ as

$$
\mathbf{n}=E_{2 a+b} \bmod \not p
$$

The kernel of $\Omega_{n}$ contains

$$
L_{+}=K \cap\left\{1+\varpi^{\prime}\left[\begin{array}{cccc}
R & R & R & R  \tag{2.5a}\\
R & R & R & R \\
R & R & R & R \\
h & R & R & R
\end{array}\right]\right\}
$$

Take $v \neq 0$ again to be fixed by $L_{+}$. Set

$$
L=K \cap\left\{1+\varpi^{\prime}\left[\begin{array}{cccc}
R & R & R & \mu^{-1}  \tag{2.5b}\\
R & R & R & R \\
R & R & R & R \\
R & R & R & R
\end{array}\right]\right\}
$$

and represent the characters of $L / L_{+}$by the cosets
$a, b \in R$. As in the previous two cases, $L v$ decomposes into irreducible $L / L_{+}$ subspaces. Choose a nonzero vector, again called $v$, which transforms by a character with $a=1$. If $b \neq 0 \bmod \nprec$, the representation $\Omega$ of $L$ on $L v$ is nondegenerate of type $(1.25 \mathrm{c})$. If $b=0 \bmod \not \ell$, the group

$$
\begin{equation*}
L_{+}=P_{\left\{s_{0}\right\}, 3 t-1} \tag{2.7a}
\end{equation*}
$$

fixes $v$. Redefine $L$ to be

$$
\begin{equation*}
L=P_{\left\{s_{0}\right\}, 3 t-2} \tag{2.7b}
\end{equation*}
$$

The cosets
$a, b, c \in R$, realize the characters of $L / L_{+}$. The decomposition of $L v$ into irreducible $L$ subspaces, produces characters with $a=1$. We can in fact assume $c=0 \bmod \nprec$. To see this, let $\tilde{\alpha}$ denote the set (2.8). The element $u(x)=u_{b}(x), x \in R$, (c.f. (1.3)) normalizes $L$ and $L_{+}$and $u(x) \tilde{\alpha} u(x)^{-1}$ is equal to

$$
\varpi^{-\iota-1}\left\{\left[\begin{array}{cccc}
0 & 0 & 0 & a \\
\varpi(b+c x) & 0 & 0 & 0 \\
\varpi c & 0 & 0 & 0 \\
0 & \varpi c & -\varpi(b+c x) & 0
\end{array}\right]+\left[\begin{array}{cccc}
\neq & \mu & \mu & \mu \\
\mu^{2} & h & h & h \\
\mu^{2} & h & \mu & \mu \\
h^{2} & \mu^{2} & \mu^{2} & \mu
\end{array}\right]\right\} .
$$

Hence, if $v \neq 0$ transforms under $L / L_{+}$by a character with $c \neq 0 \bmod \nprec$, then $w=\pi(u(-b / c)) v$ transforms under $L / L_{+}$by a character with $b=0$. Since $s_{0}$ normalizes both $L$ and $L_{+}$, the vector $\pi\left(s_{0}\right) w$ transforms under $L / L_{+}$by a character with $a=1$ and $c=0$. This proves our assertion that we can assume $c=0$. As an important consequence, we conclude the group

$$
\begin{equation*}
L_{+}=B_{4 i-2} \tag{2.9a}
\end{equation*}
$$

fixes a nonzero vector $v$. Set

$$
\begin{equation*}
L=B_{4 t-3} . \tag{2.9b}
\end{equation*}
$$

The cosets
$a, b, c \in R$, realize $\left\{L / L_{+}\right\}^{\wedge}$. The characters of $L$ which appear in $L v$ have $a=1$. Assume $v$ transforms under $L$ by such a character. If $b$, $c \neq 0 \bmod \mu$, the representation of $L$ on $L v$ is nondegenerate of type $(1.25 \mathrm{~d})$. If $c=0 \bmod \not h$, then $\pi(t) v$ is fixed by $K_{i}$ in contradiction to the hypothesis on minimality of level. If $b=0 \bmod h$, the group

$$
\begin{equation*}
L_{+}=J_{2 t-1} \tag{2.11a}
\end{equation*}
$$

fixes $v$. If $i=1$, this group is the radical $J_{1}$ of the "nonstandard" maximal compact subgroup $J$ in (1.11). Let $\sigma$ be the representation of $J / J_{1}$ on $J v$. By Harish-Chandra's philosophy of cusp forms [HC], there is a parahoric subgroup $P \subset J$ and a cuspidal representation $\Omega$ of $P / P_{1}$ such that the restriction of $\sigma$ to $P$ contains $\Omega$. Hence again, the representation ( $\pi, V$ ) contains a nondegenerate representation. Consider the alternative $i \geqslant 2$. Set

$$
\begin{equation*}
L=J_{2 \iota-2} \tag{2.11b}
\end{equation*}
$$

and realize $\left\{L / L_{+}\right\}^{\wedge}$ by the cosets
$\varpi^{-\iota-1}\left\{\left[\begin{array}{cccc}\varpi(c+b) & 0 & 0 & a \\ 0 & \varpi(c+g) & \varpi d & 0 \\ 0 & \varpi e & \varpi(c-g) & 0 \\ \varpi^{2} f & 0 & 0 & \varpi(c-b)\end{array}\right]+\left[\begin{array}{cccc}p^{2} & \not p & \nsim & \mu \\ \mu^{2} & h^{2} & h^{2} & \not p \\ \mu^{2} & h^{2} & \mu^{2} & \mu \\ \mu^{3} & h^{2} & h^{2} & h^{2}\end{array}\right]\right\}$,
$a, b, c, d, e, f, g \in R$. We can assume $L$ acts on $v$ by a character with $a=1$. Let $\tilde{\alpha}$ be the set (2.12). Both $L$ and $L_{+}$are normalized by $\underline{u}(x)=u_{-2 a-b}(x)$, $x \in R$, and $\underline{u}(x) \tilde{\alpha} \underline{u}(x)^{-1}$ is
$\varpi^{-\iota-1}\left\{\left[\begin{array}{cccc}\varpi\left(c+b^{\prime}\right) & 0 & 0 & a \\ 0 & \varpi(c+g) & \varpi d & 0 \\ 0 & \varpi e & \varpi(c-g) & 0 \\ \varpi^{2} f^{\prime} & 0 & 0 & \varpi\left(c-b^{\prime}\right)\end{array}\right]+\left[\begin{array}{cccc}p^{2} & \nsim & \mu & \mu \\ \mu^{2} & \mu^{2} & \mu^{2} & \not p \\ \mu^{2} & \mu^{2} & \mu^{2} & \mu \\ \mu^{3} & \mu^{2} & \mu^{2} & \mu^{2}\end{array}\right]\right\}$,
where $b^{\prime}=b-a x$ and $f^{\prime}=f+2 b x-a x^{2}$. Observe that the discriminant $a f+b^{2}$, is invariant, i.e., $a f+b^{2}=a f^{\prime}+b^{2}$. In our situation $a=$ $1 \bmod h$. If the discriminant is a square, say $y^{2}$, then $w=\pi(\underline{u}((b \pm y) / a)) v$
transforms under $L$ by a character of type (2.12) with $f=0$. This means $\pi(d(m, 1,1)) w$ is a $K$, fixed vector contradicting the minimal level hypothesis. Hence, we can assume $v$ transforms according to a character with $a=1$, $b=0$ and $f$ a nonsquare unit. We can take $f$ to be $\varepsilon$. Consider the eigenvalues of

$$
\left[\begin{array}{cc}
(c+g) & d \\
e & (c-g)
\end{array}\right] .
$$

We claim they do not belong to $\mathbb{F}_{q}$. To see this note that the parahoric subgroup $P_{\{, 1,\}}$ normalizes $L$ and $L_{+}$. If the eigenvalues lie in $\mathbb{F}_{q}$, then there exists an element $k \in P_{\{, j ;}$, so that $w=\pi(k) v$ transforms under $L$ by a character with $e=0 \bmod \not$. This means $\pi(t) v$ is a $K_{l}$ fixed vector, in contradiction to the minimality of level hypothesis. So, up to a twist by a one dimensional character of $G S p(4)$, there exists a vector $v \neq 0$ which transforms under $L$ by the character

$$
\varpi^{--1}\left\{\left[\begin{array}{cccc}
0 & 0 & 0 & 1 \\
0 & 0 & \varpi u & 0 \\
0 & \varpi u \varepsilon & 0 & 0 \\
\varpi^{2} \varepsilon & 0 & 0 & 0
\end{array}\right]+\left[\begin{array}{cccc}
h^{2} & h & h & h \\
h^{2} & h^{2} & h^{2} & h \\
h^{2} & h^{2} & h^{2} & h \\
h^{3} & h^{2} & h^{2} & h^{2}
\end{array}\right]\right\},
$$

$u \neq 0 \bmod \nprec$. This is of course a nondegenerate representation of type (1.25e).

In conclusion, our analysis has shown
Theorem 2.1. For any admissible representation $\pi$ of $G S p(4)$, there is a one dimensional character $\chi$ of $\operatorname{GSp}(4)$ so that $\pi \otimes \chi$ contains a nondegenerate representation in standard position.

We turn now to the question of when two nondegenerate representations can occur in the same irreducible representation of $G$. Define two nondegenerate representations $(L, \Omega),\left(L^{\prime}, \Omega^{\prime}\right)$ to be associate if
(i) $L=P, L^{\prime}=P^{\prime}$ are parahoric subgroups, $P / P_{1} \cong P^{\prime} \mid P_{1}^{\prime}$ and $\Omega \cong \Omega^{\prime}$, or
(ii) $\Omega=\Omega_{s}, \Omega=\Omega_{s^{\prime}}$ with $\mathbf{s}, \mathbf{s}^{\prime}$ of the form (1.23,24) or (1.25) and some element of $\mathbf{s}$ is conjugate to some element of $\mathbf{s}^{\prime}$.

Theorem 2.2. Suppose ( $\pi, V$ ) is an irreducible admissible representation of $G$. If $(L, \Omega),\left(L^{\prime}, \Omega^{\prime}\right)$ are two nondegenerate representations contained in $\pi$, then they are associate.

Proof. We use the intertwining principle. Let $W_{\Omega}$ and $W_{\Omega^{\prime}}$ respectively be the $\Omega$ and $\Omega^{\prime}$ subspaces of $V$. Let $E_{\Omega^{\prime}}$ denote the projection from $V$ onto $W_{\Omega^{\prime}}$. Since $\pi$ is irreducible, there is a $g \in G$ such that

$$
I=E_{\Omega^{\prime}} \pi(g): W_{\Omega} \rightarrow W_{\Omega^{\prime}}
$$

is nonzero, and for $h \in L \cap g L^{\prime} g^{-1}, I \Omega(h)=\Omega^{\prime}\left(g^{-1} h g\right) I$. We consider three cases according to whether none, one or both $L, L^{\prime}$ are parahoric subgroups. Case $1, \Omega=\Omega_{\mathrm{s}}, \Omega^{\prime}=\Omega_{\mathbf{s}^{\prime}}$. Write $\mathbf{s}=s+\mathfrak{I}, \mathbf{s}^{\prime}=s^{\prime}+\mathfrak{I}$. Observe that

$$
L \cap g L^{\prime} g^{-1}=c\left(I^{*} \cap g I^{\prime *} g^{-1}\right)
$$

Therefore, if $y \in I^{*} \cap g I^{\prime *} g^{-1}$, then

$$
\psi(\langle y,-s\rangle / 2)=\Omega_{\mathbf{s}}(c(y))=\Omega_{\mathbf{s}^{\prime}}\left(g^{-1} c(y) g\right)=\psi\left(\left\langle y,-g s^{\prime} g^{-1}\right\rangle / 2\right)
$$

This means $\operatorname{tr}\left(y\left(s-g s^{\prime} g^{-1}\right)\right) \in R$ for all $y \in I^{*} \cap g I^{\prime *} g^{-1}$. We conclude $s-g s^{\prime} g^{-1} \in\left\{I^{*} \cap g I^{\prime *} g^{-1}\right\}^{*}=I+g I^{\prime} g^{-1}$, i.e., $\mathbf{s}$ and $g \mathbf{s}^{\prime} g^{-1}$ intersect.
Case $2, \Omega=\Omega_{\mathrm{s}}$ and $L^{\prime}=P^{\prime}$ a parahoric subgroup. We show $\Omega$ and $\Omega^{\prime}$ cannot both occur in $\pi$ by showing that $\Omega$ and the trivial representation of $P_{1}^{\prime}$ cannot occur simultaneously in $\pi$. The trivial character of $P_{1}^{\prime} / P_{2}^{\prime}$ can realized as $\Omega_{\mathbf{s}^{\prime}}$ with $\mathbf{s}^{\prime}=\mathrm{I}$ and $P_{1}^{\prime}=c\left(\mathrm{I}^{*}\right)$. By the same reasoning as in case 1 , some element of $\mathbf{s}$ must be conjugate to some element of $\mathbf{s}^{\prime}$. This is impossible because the minimum valuation of the eigenvalues of each element in $\mathbf{s}$ differ from those of $\mathbf{s}^{\prime}$ (see Theorem 6.1 [HM2]).
Case $3, L$ and $L^{\prime}$ both parahoric subgroups. The reasoning again is based on the intertwining principle. It has already been done by Harish Chandra (see [HC]).

## 3. Level one representations

In this and the next two sections, we shall give a fairly detailed description of the irreducible representations of $G$. In light of Theorem 2.1, it suffices to describe the irreducible representations of $G$ which contain a given nondegenerate representation $(L, \Omega)$. To accomplish this goal, we investigate the Hecke algebra $\mathscr{H}(G / / L, \Omega)$. In preparation for this analysis, we briefly recall some relevant facts about Hecke algebras and their place in our classification of the representations of $G$.

Let $Q$ be an arbitrary open compact subgroup of $G$ and let $\left(\sigma, V_{\sigma}\right)$ be an irreducible representation of $Q$. The Hecke algebra $\mathscr{H}=\mathscr{H}(G / / Q, \sigma)$ consists of the functions $f: G \rightarrow$ End $V_{\sigma}$ such that
(i) $f$ is compactly supported
(ii) $f\left(k g k^{\prime}\right)=\sigma(k) f(g) \sigma\left(k^{\prime}\right), g \in G$ and $q, q^{\prime} \in Q$.

An element $g$ in $G$ is said to lie in the support of $\mathscr{H}$ if there is a $f \in \mathscr{H}$ which is nonzero at $g$. The support set of $\mathscr{H}$ is denoted by supp $\mathscr{H}$. The algebra $\mathscr{H}$ is of course an algebra under convolution. If Haar measure is normalized so that $\operatorname{vol}(Q)=1$, then the function

$$
e_{\sigma}(g)=\left\{\begin{array}{cc}
\sigma(g) & g \in Q \\
0 & g \notin Q
\end{array}\right.
$$

is the identity element of $\mathscr{H}$. If $(\pi, V)$ is any admissible representation of $G$, consider the tensor product space $W=V \otimes V_{\sigma}$. The Hecke algebra $\mathscr{H}$ acts on $W$ by the formula

$$
\pi(f)(v \otimes w)=\int_{G} \pi(g) v \otimes f(g) w \mathrm{~d} g
$$

$f \in \mathscr{H}, v \in V$ and $w \in V_{\sigma}$. Observe that if $k \in Q$, then

$$
\begin{aligned}
\pi(f)(\pi(k) v \otimes \sigma(k) w) & =\int_{G} \pi(g) \pi(k) v \otimes f(g) \sigma(k) w \mathrm{~d} g \\
& =\int_{G} \pi(g k) v \otimes f(g k) w \mathrm{~d} g \\
& =\pi(f)(v \otimes w) \\
& =(\pi(k) \otimes \sigma(k)) \pi(f)(v \otimes w) .
\end{aligned}
$$

In particular, the actions of $\mathscr{H}$ and $Q$ on $W$ commute; hence, $\mathscr{H}$ acts on the finite dimensional space $E=W^{Q}$. It is not difficult to see that the dimension of $E$ is equal to the multiplicity of the contragredient representation $\sigma^{t}$ in $\pi$ and additionally, if $\pi$ is irreducible, then the representation of $\mathscr{H}$ on $E$ is also irreducible. The process of passing from $V$ to $E$ is a bijection between the irreducible admissible representations of $G$ which contain $\sigma^{t}$ with positive multiplicity and the irreducible finite dimensional representations of $E$. As an upshot of these considerations and Theorem 2.1, the problem of determining the representations of $G$ is equivalent to determining the representations of the Hecke algebras $\mathscr{H}(G / / L, \Omega)$, where $(L, \Omega)$ is a nondegenerate
representation. We show these Hecke algebras (actually very closely related Hecke algebras $\mathscr{H}(G / / J, \sigma))$ are isomorphic to Hecke algebras of smaller groups. This allows a transfer of representations between the groups.

We also remark that $\mathscr{H}$ possess a natural involutive ${ }^{*}$-operation. It is defined for $f \in \mathscr{H}$ by

$$
\begin{equation*}
f^{*}(g)=f\left(g^{-1}\right)^{*} \tag{3.1}
\end{equation*}
$$

The * on the right side is the adjoint operation on End $V_{\sigma}$. The inner product

$$
\begin{equation*}
\left\langle f_{1}, f_{2}\right\rangle=\operatorname{tr}\left\{f_{1} * f_{2}^{*}(1)\right\} . \tag{3.2}
\end{equation*}
$$

on $\mathscr{H}$ provides a context in which the Plancherel Formula can be formulated (see Appendix 1 [HM1]). The Hecke algebra isomorphisms established shall preserve the $L_{2}$ structure of the algebras and so the transfer of representations will preserve the property of square integrability. The isomorphisms shall also preserve the support of the Hecke algebras. This means the transfer of representations will preserve supercuspidality (see [HM1]).

We now give a description of the Hecke algebras $\mathscr{H}=\mathscr{H}(G / / P, \Omega)$ when $P$ is a parahoric subgroup of the form (1.11) and $\Omega$ is a cuspidal representation of $P / P_{1}$.

We need to review various properties of the Bruhat decomposition [BT]. Let $W^{\text {aff }}=N / \mathbf{A}(R)$ be the affine Weyl group defined in (1.8). For $w \in N$, let $\mathbf{w}$ denote the image of $w$ in $W^{\text {aff }}$. Each double coset of $B$ in $G$ can be written in the form $B w B, w \in N$. Two double cosets $B w B$ and $B w^{\prime} B$ are equal precisely when $\mathbf{w}=\mathbf{w}^{\prime}$ in $W^{\text {aff }}$. This decomposition is written symbolically as

$$
\begin{equation*}
G=B W^{\mathrm{aff}} B \tag{3.3}
\end{equation*}
$$

The length of an element $w$ in $N$ is the integer $\ell(w)$ such that

$$
\begin{equation*}
[B w B: B]=q^{f(w)} \tag{3.4}
\end{equation*}
$$

The length can also be interpreted as the number of reflections, i.e., elements of $S$, in a reduced expression for $\mathbf{w}$. The elements in $S$ all have length 1. Also

> (i) $B w B w^{\prime} B=B w w^{\prime} B, \quad \ell(w)+\ell\left(w^{\prime}\right)=\ell\left(w w^{\prime}\right)$
> (ii) $B w B s B=B w B \cup B w s B, \quad s \in S$ and $\ell(w s)=\ell(w)-1$.

We remark that it is possible to choose a set of representatives $\{w\}$ for $W^{\text {aff }}$ in a fashion so that if $w$ and $w^{\prime}$ are the representatives for $\mathbf{w}$ and $\mathbf{w}^{\prime}$, then
$w w^{\prime}$ is the representative for $\mathbf{w} \mathbf{w}^{\prime}$ when $\ell(w)+\ell\left(w^{\prime}\right)=\ell\left(w w^{\prime}\right)$.
Similar results hold for parahoric subgroups. In the parahoric case, if $P$ is generated by $B$ and the set of reflections $I \subset S$, let $W_{I} \subset W^{\text {aff }}$ be the subgroup generated by the reflections in $I$. Then, the double cosets of $P$ in $G$ are in one-one correspondence with the double cosets of $W_{I}$ in $W^{\text {aff }}$.

For a parahoric subgroup $P=P_{I}$, let

$$
\begin{align*}
M= & \text { subgroup of } P \text { generated by } \mathbf{A}(R) \text { and the subgroups } \\
& U_{c, i} \subset P \text { such that } U_{-c,-i} \subset P . \tag{3.7}
\end{align*}
$$

If $I \subset\left\{s_{0}, s_{1}\right\}$, then $M=\mathbf{M}_{I}(R)$ and $P / P_{1}=\mathbf{M}_{l}\left(\mathbb{F}_{q}\right)$. In all cases $P_{I}=M P_{I, 1}$. The next result gives a condition $w$ must satisfy in order to lie in the support of $\mathscr{H}$.

Theorem 3.1. (Harish-Chandra). A necessary condition for $P w P$ to lie in the support of $\mathscr{H}(G / / P, \Omega), \Omega$ a cuspidal representation of $P / P_{1}$ is that w normalizes M, i.e.

$$
w M w^{-1}=M
$$

Proof. For $w \in W^{\text {aff }}$, let $H=\left\{w P w^{-1} \cap P\right\} P_{1} / P_{1}$. The group $H$ is a parabolic subgroup of $P / P_{1}$. Suppose $w \in \operatorname{supp} \mathscr{H}$, and $H \neq P / P_{1}$. Let $U$ be the unipotent radical of $H$. The representation $\Omega^{w}$ of $\left\{w P w^{-1} \cap P\right\}$ is trivial on $w P w^{-1} \cap P_{1}$ and so can be viewed as a representation of $H$. This representation is trivial on $U$ and when induced to $P / P_{1}$ will intertwine with $\Omega$. This of course contradicts cuspidality of $\Omega$. Therefore, $H=P / P_{1}$. This is equivalent to $w M w^{-1}=M$.

We turn to the individual cases in (1.11).
$P=P_{\left\{s_{0}, s_{1}\right\}}$. Here, the group $M$ in (3.7) is $\mathbf{G}(R)$ and $P / P_{1}=\mathbf{G}\left(\mathbb{F}_{q}\right)$. Let $Z \subset G$ be the group of scalar matrices. It is an immediate consequence of Theorem 3.1 that supp $\mathscr{H}(G / / P, \Omega)=Z K$. Set $G^{\prime}=Z$ and $P^{\prime}=G^{\prime} \cap P$. For $z \in Z$, let $e_{z}$ (resp. $f_{z}$ ) denote the function in $\mathscr{H}^{\prime}=\mathscr{H}\left(G^{\prime} / / P^{\prime}\right)$ (resp. $\mathscr{H}=\mathscr{H}(G / / P, \Omega)$ ) whose support is $P^{\prime} z P^{\prime}($ resp. $P z P)$ and whose value at $z$ is 1 (resp. the identity operator). Then,

Proposition 3.2. The map $\eta: \mathscr{H}^{\prime} \rightarrow \mathscr{H}$ given by

$$
\eta\left(e_{z}\right)=f_{z}
$$

is $a^{*}$-isomorphism of algebras.
Remarks. (a) The center $Z$ of $G$ is of course not compact. In order to speak of square-integrable and supercuspidal representations of $G \bmod Z$, let $I$ be the identity matrix in $G$, and let $T$ denote the subgroup of $G$ generated by the scalar $\varpi I$, i.e.,

$$
\begin{equation*}
T=\left\{\varpi^{n} I \mid n \in \mathbb{Z}\right\} \tag{3.8}
\end{equation*}
$$

The group $G / T$ has a compact center and given an irreducible representation $(\pi, V)$ of $G$, there is a unique unramified one dimensional character of $G$ such that $\pi \otimes \chi$ factors to a representation of $G / T$. The representation $\pi$ is square integrable (resp. supercuspidal) $\bmod Z$ precisely when $\pi \otimes \chi$ is as a representation of $G / T$. The formal degree of $\pi$ is then the formal degree of $\pi \otimes \chi$.
(b) A result such as Proposition 3.2 yields a similar result for the group $G / T$. This is done by extending $\Omega$ trivially to $T$ and integrating functions in $\mathscr{H}\left(G^{\prime} / / P^{\prime}\right)$ (resp. $\left.\mathscr{H}(G / / P, \Omega)\right)$ over $T$ to obtain functions in $\mathscr{H}\left(G^{\prime} / / T P^{\prime}\right)$ (resp. $\mathscr{H}(G / / T P, \Omega)$ ). The map $\eta$ will integrate over $T$ to yield a *-isomorphism from $\mathscr{H}\left(G^{\prime} / / T P^{\prime}\right)$ to $\mathscr{H}(G / / T P, \Omega)$. In our specific situation, since $G^{\prime}=T P^{\prime}$, the algebra $\mathscr{H}\left(G^{\prime} \| T P^{\prime}\right)$ is the complex numbers $\mathbb{C}$. This means that any irreducible admissible representation $(\pi, V)$ of $G$ which contains $\Omega$ on restriction to $T P$ is in fact equivalent to ind $_{T P^{\dagger} G} \Omega$. In particular, as a representation of $G / T, \pi$ is supercuspidal and has formal degree

$$
\begin{equation*}
d_{\pi}=(\operatorname{deg} \Omega) / \operatorname{vol}(T P / T) \tag{3.9}
\end{equation*}
$$

The formal degree is of course related to the normalization of Haar measure via vol $(T P / T)$.
$P=P_{\left\{r_{0}, x_{2}\right\}}$. Recall that

$$
\begin{equation*}
P / P_{1}=\left\{\left(g_{1}, g_{2}\right) \in \mathbf{G} \mathbf{L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) \times \mathbf{G} \mathbf{L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) \mid \operatorname{det} g_{1}=\operatorname{det} g_{2}\right\} \tag{3.10}
\end{equation*}
$$

The element $t$ of (1.9) determines an automorphism of $P / P_{1}$; it interchanges $g_{1}$ and $g_{2}$. Let $Z^{\prime}$ be the group generated by $Z$ and $t$. The support of $\mathscr{H}=\mathscr{H}(G / / P, \Omega)$ is easily seen to be either $Z P$ or $Z^{\prime} P$ depending on
whether $\Omega$ is fixed under the automorphism induced by $t$. Set $G^{\prime}=Z$ or $Z^{\prime}$ accordingly. Let $P^{\prime}=G^{\prime} \cap P$. For $z \in Z$, let $e_{z}$ (resp. $f_{z}$ ) be the function in $\mathscr{H}^{\prime}=\mathscr{H}\left(G^{\prime}| | P^{\prime}\right)($ resp. $\mathscr{H})$ with value 1 (resp. identity operator) at $z$ and support $z J^{\prime}$ (resp. $z J$ ). In case $G^{\prime}=Z^{\prime}$, let ${ }^{\top}$ be an element in End $V_{\Omega}$ such that i) $J \Omega(g)=\Omega\left(\operatorname{tg}^{-1}\right) \mathcal{J}$ and ii) $J^{2}=I$, the identity operator. Let $e_{z t}$ (resp. $f_{z t}$ ) be the function in $\mathscr{H}^{\prime}$ (resp. $\mathscr{H}$ ) with value 1 (resp. operator $J^{J}$ ) at $z t$ and support $P^{\prime} z t P^{\prime}($ resp. $P z t P)$.

Proposition 3.3. The map $\eta: \mathscr{H}^{\prime} \rightarrow \mathscr{H}$ defined by

$$
\eta\left(e_{z}\right)=f_{z} \text { and } \eta\left(e_{z t}\right)=f_{z t}
$$

is a*-isomorphism of algebras.
The remarks after Proposition 3.2 apply here also. Extend $\Omega$ to $T P$ by letting $\Omega$ act trivially on $T$. If $G^{\prime}=Z$, then any irreducible admissible representation $(\pi, V)$ of $G$ which contains $\Omega$ on restriction to $T P$ is equivalent to $\operatorname{ind}_{T P T_{G}} \Omega$. As a representation of $G / T, \pi$ is supercuspidal and its formal degree is given by (3.9). If $G^{\prime}=Z^{\prime}$, then $\operatorname{ind}_{T P^{p} G} \Omega$ decomposes into two supercuspidal representations, corresponding to the two extensions of $\Omega$ to $Z^{\prime} P$. The formal degree of these two representations is

$$
\begin{equation*}
(\operatorname{deg} \Omega) / \operatorname{vol}\left(Z^{\prime} P / T\right) . \tag{3.11}
\end{equation*}
$$

Case $P=B=P_{\varnothing}$. The group $M$ in (3.7) is $\mathbf{A}(R)$. For convenience, we identify $P / P_{1}$ and $\mathbf{A}\left(\mathbb{F}_{q}\right)$. Under this identification, a cuspidal representation of $P / P_{1}$ is a linear character $\Omega$ of the group $\mathbf{A}\left(\mathbb{F}_{q}\right)$. The character $\Omega$ can be factored into the product of three characters $\chi, \theta$ and $\varphi$. In the notation of (1.1), $\chi, \theta$ and $\varphi$ are characters which depend only on the components $a, b$ and $c$ respectively. The normalizer of $\mathbf{A}(R)$ is the group $N$ of monomial matrices. Up to conjugacy, the stabilizer Stab ( $\Omega$ ) of $\Omega$ in $N$ is one of five groups:
(i) $N$
(ii) $A=\mathbf{A}(F)$
(iii) $A \cup s_{0} A$
(iv) $A \cup s_{1} A$
(v) $A \cup s_{1} A \cup s_{0} s_{1} s_{0} A \cup s_{0} s_{1} s_{0} s_{1} A$.

Let sgn denote the order 2 character of $\mathbb{F}_{q}^{\times}$. The relation among the characters $\chi, \theta$ and $\varphi$ in the various cases are:
(i) $\chi=\theta / \varphi=1$
(ii) $\Omega$ regular
(iii) $\chi \neq \theta / \varphi=1$
(iv) $\chi=\theta / \varphi \neq \operatorname{sgn}$ or 1
(v) $\chi=\theta / \varphi=\operatorname{sgn}$.

We give a description of the Hecke algebra $\mathscr{H}=\mathscr{H}(G / / B, \Omega)$ based on these five cases.

Observe that since $\Omega$ is one dimensional, for $g \in \operatorname{supp} \mathscr{H}$, there is a unique function $e_{g} \in \mathscr{H}$ with support $B g B$ and $e_{g}(g)=1$. By the Bruhat decomposition any double coset $B g B$ is of the form $B w B$ for some $w \in W^{\text {aff }}$. Therefore, if $W^{\prime}=\operatorname{Stab}(\Omega)$, then

$$
\operatorname{supp} \mathscr{H}=B W^{\prime} B
$$

Remark. We shall see that only cases i) and v) contain discrete series representations of $G / T$. In each case, $G / T$ has four such representations. These are described in (3.14), (3.16), and (3.58).

Case ( $i$ ). Up to twisting by a one dimensional character of $G$, we can assume $\Omega$ is the trivial character. The following result of Iwahori and Matsumoto [1] gives a description of $\mathscr{H}$ in terms of generators and relations.

Theorem 3.4. The algebra $\mathscr{H}(G / / B)$ is generated by

$$
e_{\imath}, s \in\left\{s_{0}, s_{1}, s_{2}, t\right\}
$$

The elements $e_{w}$ satisfy the relations
(a) $e_{w^{\prime}} * e_{w^{\prime}}=e_{w n^{\prime}} \quad \ell\left(w w^{\prime}\right)=\ell(w)+\ell\left(w^{\prime}\right)$
(b) $e_{s} * e_{s}=q+(q-1) e_{s} \quad s \in\left\{s_{0}, s_{1}, s_{2}\right\}$
(c) (i) $e_{s_{0}} * e_{\varsigma_{1}} * e_{s_{0}} * e_{\varsigma_{1}}=e_{s_{1}} * e_{\varsigma_{0}} * e_{s_{1}} * e_{\varsigma_{0}}$
(ii) $e_{1_{1}} * e_{s_{2}} * e_{\imath_{1}} * e_{\imath_{2}}=e_{\imath_{2}} * e_{s_{1}} * e_{s_{2}} * e_{\imath_{1}}$
(d) (i) $e_{t} * e_{t}=e_{\varpi I}$
(ii) $e_{t} * e_{s_{0}}=e_{s_{2}} * e_{t}$
(iii) $e_{t} * e_{s_{1}}=e_{s_{1}} * e_{t}$.

There are four square integrable representations of $G / T$ which contain the trivial representation of $B$. We describe the representation of $\mathscr{H}$ corresponding to these representations. In the first two cases, the so-called special
representations, the representation $\pi$ of $\mathscr{H}$ is one dimensional. In terms of the generators given in (1.6) and (1.9)

$$
\begin{equation*}
\pi\left(e_{,}\right)=-1 \quad s \in S \quad \text { and } \quad \pi\left(e_{t}\right)= \pm 1 \tag{3.14}
\end{equation*}
$$

The formal degree of the two special representations are both

$$
\begin{align*}
d_{\pi} & =\left\{\sum_{w \in W^{* \pi} / T} q^{-/(x)}\right\}^{-1} \operatorname{vol}(B)^{-1}  \tag{3.15}\\
& =\left\{\left(q^{3}-1\right)(q-1) /\left\{2\left(q^{2}+1\right)(q+1)^{2}\right\}\right\} / \operatorname{vol}(B)
\end{align*}
$$

The remaining two square integrable representations were first constructed by Borel $[\mathrm{B}]$. The representation of $\mathscr{H}$ is two dimensional in each case. Here,

$$
\begin{align*}
& \pi\left(e_{s_{0}}\right)=\left[\begin{array}{rr}
q & 0 \\
0 & -1
\end{array}\right] \pi\left(e_{e_{1}}\right)=\left[\begin{array}{rr}
-1 & 0 \\
0 & -1
\end{array}\right]  \tag{3.16}\\
& \pi\left(e_{12}\right)=\left[\begin{array}{rr}
-1 & 0 \\
0 & q
\end{array}\right] \pi\left(e_{t}\right)= \pm\left[\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right]
\end{align*}
$$

These two representations have the same formal degree. It is

$$
\begin{equation*}
\left\{(q-1)^{2} /\left\{2 q(q+1)^{2}\right\}\right\} / \operatorname{vol}(B) . \tag{3.17}
\end{equation*}
$$

Upon restriction to $S p(4) \subset G$, these representations decompose into two irreducible components.

Case (ii) $\Omega$ regular. To describe the structure of $\mathscr{H}$, which will turn out to be a group algebra, we need a preliminary result. Let

$$
\begin{align*}
& U_{+}=\prod_{<>0} U_{c, 0} \text { and } U_{-}=\prod_{\ll 0} U_{c, 1} . \\
& A^{+}=\left\{a \in A \mid a^{-1} U_{+} a \subset U_{+}\right\}  \tag{3.18}\\
& A^{-}=\left\{a \in A \mid a^{-1} U_{-} a \subset U_{-}\right\}=\left\{a \mid a^{-1} \in A^{+}\right\} .
\end{align*}
$$

Note that $B=\mathbf{A}(R) U_{+} U_{-}$.

Proposition 3.5. For $h \in A$, and $a \in A^{+}$or $A^{-}$,
$B h B a B \cap B A B=B h a B$.

Proof. We recall a sharp form of the Bruhat decomposition (3.3). For $w \in N$ and $c \in \Phi$, let $w(c)$ be the root so that $w U_{c} w^{-1}=U_{n(c)}$. Let

$$
\begin{align*}
& C_{+}=\left\{c \in \Phi \mid w\left(U_{c} \cap B\right) w^{-1} \nsubseteq B\right\} \\
& C_{-}=\left\{c \in \Phi \mid w^{-1}\left(U_{c} \cap B\right) w \nsubseteq B\right\}  \tag{3.19}\\
& C_{0}=\left\{c \in \Phi \mid w\left(U_{c} \cap B\right) w^{-1}=U_{w(c)} \cap B\right\} \\
& C_{0}=w^{-1} C_{0} w .
\end{align*}
$$

Each element $g$ in $B w B$ can be written uniquely in the form

$$
\begin{equation*}
g=u_{-} d w u_{0} u_{+}=u_{-} u_{0}^{\prime} w d^{\prime} u_{+} \tag{3.20}
\end{equation*}
$$

where $d, d^{\prime} \in \mathbf{A}(R)$ and $u_{-}, u_{+}, u_{0}$ and $u_{0}^{\prime}$ respectively are a product of elements in $\left\{U_{c} \mid c \in C_{-}\right\},\left\{U_{c} \mid c \in C_{+}\right\},\left\{U_{c} \mid c \in C_{0}\right\}$ and $\left\{U_{c} \mid c \in C_{0^{\prime}}\right\}$. Similar decompositions hold for parahoric subgroups $P_{S^{\prime}}$ and $w^{\prime} s$ in the normalizer of the group $M_{S^{\prime}}$. We now prove the proposition when $a \in A^{+}$. Each $g \in B a B$ can be written uniquely as

$$
g=u_{L} a d u_{U}
$$

with $u_{L} \in U_{-}, u_{U} \in U_{+}$and $d \in \mathbf{A}(R)$. This means $B h B a B$ is a union

$$
B h B a B=\cup B h u_{L} a B \quad\left(u_{L} \in U_{-}\right)
$$

Suppose $x \in h B a \cap B A B$, say $x=b h^{\prime} b^{\prime}$. Write this as

$$
h u_{L} a=u_{-} u_{+} d h^{\prime} d^{\prime} u_{+}^{\prime} u_{-}^{\prime},
$$

where $u_{-}, u_{-}^{\prime} \in U_{-} ; u_{+}, u_{+}^{\prime} \in U_{+} ;$and $d, d^{\prime} \in \mathbf{A}(R)$. Thus

$$
\begin{equation*}
u_{-}^{-1} h u_{L} a u_{-}^{\prime-1}=u_{+} d h^{\prime} d^{\prime} u_{+}^{\prime} \tag{3.21}
\end{equation*}
$$

It is obvious from (3.21) that $B h B a B \cap B A B=B h a B$.

Every element of $A$ is the product of an element in $A^{+}$and an element in $A^{-}$; therefore,

$$
\begin{equation*}
f_{g} * f_{g^{\prime}}=\text { multiple of } f_{g g^{\prime}} \tag{3.22}
\end{equation*}
$$

is an immediate consequence of Proposition 3.5. Our next goal is to establish a quantitative version of (3.22) to obtain the precise multiplicative structure of $\mathscr{H}$. To do this, let

$$
\begin{align*}
d_{+} & =\varpi^{-1}\left(E_{1,1}+E_{2,2}\right)+\left(E_{3,3}+E_{4,4}\right) \\
& =t^{-1} s_{0} s_{1} s_{0} d(-1,-1,1) \\
d_{-} & =d_{+}^{-1}  \tag{3.23}\\
h_{+} & =\varpi^{-1} E_{1,1}+\left(E_{2,2}+E_{3,3}\right)+\varpi E_{4,4}=s_{2} s_{1} s_{0} s_{1} \\
h_{-} & =h_{+}^{-1} .
\end{align*}
$$

Proposition 3.6. For $h \in A$

$$
\begin{aligned}
& f_{d_{+}} * f_{h}=q^{\left\{\left(\left(d_{+}\right)+\left((h)-\left(\left(d_{+} h\right) \mid / 2\right.\right.\right.\right.} f_{d_{+} h}=f_{h} * f_{d_{+}} \\
& f_{h_{+}} * f_{h}=q^{\left\{\left(\left(h_{+}\right)+\left((h)-<\left(\left(h_{+} h\right) \mid / 2\right.\right.\right.\right.} f_{h_{+} h}=f_{h} * f_{h_{+}} .
\end{aligned}
$$

Proof. We know that $f_{d_{+}} * f_{h}$ is equal to a multiple of $f_{d_{+}+}$. To determine the multiple, we evaluate $f_{d_{+}} * f_{h}$ at $d_{+} h$. We find

$$
f_{d_{+}} * f_{h}\left(d_{+} h\right)=\int_{G} f_{d_{+}}(g) f_{h}\left(g^{\prime}\right) \mathrm{d} g, \quad \text { where } \quad g g^{\prime}=d_{+} h
$$

The integrand is nonzero if and only if $g \in B d_{+} B$ and $g^{\prime} \in B h B$. Thus, we need to determine those $g$ (resp. $g^{\prime}$ ) in $B d_{+} B$ (resp. BhB) such that $g g^{\prime}=d_{+} h$. We use (3.20). In our particular case of $B d_{+} B$, each element $g$ can be written uniquely as

$$
g=u d d_{+} v
$$

where $d \in \mathbf{A}(R), v \in U_{+} U_{-a, 1}$ and $u \in U_{-b, 1} U_{-a-b, 1} U_{-2 a-b, 1}$. Similarly, for $h$, let $C_{-}, C_{0^{\prime}}$ and $C_{+}$be the sets in (3.19). Each element $g^{\prime}$ of $B h B$ is uniquely of the form

$$
g^{\prime}=u^{\prime} h d^{\prime} v^{\prime}
$$

where $u^{\prime}$ (resp. $v^{\prime}$ ) is a product of elements in $U_{c}, c \in C_{-} \cup C_{0^{\prime}}$ (resp. $U_{c}$, $c \in C_{+}$) and $d^{\prime} \in \mathbf{A}(R)$. The product $g g^{\prime}=d_{+} h$ is thus equivalent to $u d d_{+} v u^{\prime} h d^{\prime} v^{\prime}=d_{+} h$, i.e.,

$$
\begin{equation*}
d v u^{\prime} d^{\prime}=d_{+}^{-1} u^{-1} d_{+} h v^{-1} h^{-1} \tag{3.24}
\end{equation*}
$$

With the obvious notation, write $u=u_{-b} u_{-a-b} u_{-2 a-b}$. Then, (3.24) implies $u_{c} \in U_{\iota, 2}$ when $c \notin C_{+}$. This is the only condition placed on $u$. Therefore, $f_{d_{+}} * f_{h}\left(d_{+} h\right)=q^{3-\beta}$, where $\beta=\#\left\{\{-b,-a-b,-2 a-b\} \cap C_{+}\right\}$, i.e.,

$$
f_{d_{+}} * f_{h}=q^{\left\{f\left(d_{+}\right)+f(h)-f\left(d_{+} h\right)\right\} / 2} f_{d_{+} h} .
$$

The other relations are proved by the same type of reasoning.

Since $d_{+}$and $h_{+}$generate $A \bmod \mathbf{A}(R)$, we conclude

Proposition 3.7. For $w, w^{\prime} \in A$,

$$
f_{w^{\prime}} * f_{w^{\prime}}=q^{\left\{t\left(w^{\prime}\right)+f\left(w^{\prime}\right)-f\left(w w^{\prime}\right)\right\} / 2} f_{w w^{\prime}}
$$

Let $G^{\prime}=A$ and $B^{\prime}=A \cap B$. In this setup, the support of $\mathscr{H}$ is $B G^{\prime} B$ and the Hecke algebra $\mathscr{H}^{\prime}=\mathscr{H}\left(G^{\prime} \| B^{\prime}\right)$ is the group algebra. Let $e_{x}, w \in A$, denote the characteristic function of $w B^{\prime}$. The next result exhibits an isomorphism between $\mathscr{H}$ and $\mathscr{H}^{\prime}$ similar to the isomorphisms found in [HM1] and [M1].

Corollary 3.8. The map $\eta: \mathscr{H}^{\prime} \rightarrow \mathscr{H}$ defined by

$$
\eta\left(e_{n}\right)=q^{-f(x) / 2} f_{w}
$$

is $a^{*}$-isomorphism of algebras.

Remark. The map $\eta$ of course effects a transfer between the irreducible representations of $G$ containing $\Omega^{t}$ and the irreducible representations, i.e., characters of $G^{\prime} / B^{\prime}$. Furthermore, since $\eta$ is a ${ }^{*}$-isomorphism, the transfer of representations will preserve Plancherel Measure (see [M1]). An important consequence of the transfer is the following: since $G^{\prime} / T$ has no discrete series, there are none of $G / T$ containing $\Omega^{t}$.

Case (iii) $\chi \neq \theta / \varphi=1$. Let

$$
\begin{align*}
& r_{0}=s_{0} \\
& r_{1}=E_{1,1}-\varpi^{-1} E_{2,3}+\varpi E_{3,2}+E_{4,4}=s_{1} s_{2} s_{1}  \tag{3.25}\\
& h_{+}, h_{-} \text {as in }(3.23) \\
& t^{\prime}=\varpi E_{1,1}+E_{2,3}+\varpi E_{3,2}-E_{4,4}=s_{1} s_{0} t .
\end{align*}
$$

The elements $r_{0}$ and $r_{1}$ generate an infinite dihedral subgroup $W_{r}^{\prime} \subset W^{\prime}$. Let $W_{s}^{\prime}$ be the subgroup of $W^{\prime}$ generated by $h_{+}$and $\varpi I$. The group $W_{s}^{\prime}$ is in the center of $W^{\prime}$ and

$$
\begin{equation*}
W_{r}^{\prime} \cap W_{s}^{\prime}=\{1\}, \quad W^{\prime}=W_{r}^{\prime} W_{s}^{\prime} \cup t^{\prime} W_{r}^{\prime} W_{s}^{\prime} \tag{3.26}
\end{equation*}
$$

In particular, any element $w^{\prime}$ of $W^{\prime}$ can be written uniquely in the form

$$
\begin{equation*}
w^{\prime}=d w t^{\prime m}, \quad d \in W_{r}^{\prime}, \quad w \in W_{s}^{\prime} \quad \text { and } \quad m \in\{0,1\} . \tag{3.27}
\end{equation*}
$$

Let $\ell^{\prime}$ be the length function on $W_{r}^{\prime}$, i.e., for $w \in W_{r}^{\prime}, \ell^{\prime}(w)$ is equal to the number of $r_{0}$ 's and $r_{1}$ 's in a reduced word expression for $w$. It is easy to verify that $\ell^{\prime}\left(w w^{\prime}\right)=\ell^{\prime}(w)+\ell^{\prime}\left(w^{\prime}\right), w, w^{\prime} \in W_{h}{ }^{\prime}$, iff $\ell\left(w w^{\prime}\right)=\ell(w)+\ell\left(w^{\prime}\right)$. Consequently

$$
\begin{equation*}
f_{w^{\prime}} * f_{w^{\prime}}=f_{w w^{\prime}} \quad \text { when } \quad w, w^{\prime} \in W_{r}^{\prime} \quad \text { and } \quad \ell^{\prime}\left(w w^{\prime}\right)=\ell^{\prime}(w)+\ell^{\prime}\left(w^{\prime}\right) \tag{3.28}
\end{equation*}
$$

We prove an analogue of Proposition 3.7.
Proposition 3.9. For $d \in W_{’}^{\prime}, w \in W_{r}^{\prime}, f_{d}$ and $f_{w}$ commute. For $g \in\left\{1, t^{\prime}\right\}$

$$
\left\{q^{-f(d) / 2} f_{d}\right\} *\left\{q^{-f(w) / 2} f_{w}\right\} *\left\{q^{-f(g) / 2} f_{g}\right\}=q^{-f(d w g) / 2} f_{d v g} .
$$

Proof. We first establish some special cases of the Proposition. We can assume the element $d$ is a power of $h_{+}$or $h_{-}$. If $h$ is either $h_{+}$or $h_{-}$, we have $B h^{m} B=\{B h B\}^{m}$, hence

$$
\begin{equation*}
f_{h^{m}}=f_{h}^{m} \tag{3.29}
\end{equation*}
$$

Consider $f_{h_{+}} * f_{r_{0} r_{1}}$. Since

$$
\begin{align*}
B h_{+} B r_{0} r_{1} B & =B s_{2} s_{1} s_{0} s_{1} B s_{0} s_{1} s_{2} s_{1} B=B s_{2} s_{1} s_{0} s_{1} s_{0} B s_{1} s_{2} s_{1} B \\
& =\left(B s_{2} s_{1} s_{0} s_{1} s_{0} B \cup B s_{2} s_{0} s_{1} s_{0} B\right) s_{2} s_{1} B  \tag{3.30}\\
& =B s_{2} s_{1} s_{0} s_{1} s_{0} s_{2} s_{1} B \cup B s_{2} s_{0} s_{1} s_{0} s_{2} s_{1} B
\end{align*}
$$

we have $B h_{+} B r_{0} r_{1} B \cap \operatorname{supp} \mathscr{H}=B h_{+} r_{0} r_{1} B$, so $f_{h_{+}} * f_{r_{0} r_{1}}$ is a multiple of $f_{h_{+} r_{0} r_{1}}$. Evaluating $f_{h_{+}} * f_{r_{0} r_{1}}$ at $h_{+} r_{0} r_{1}$ gives

$$
\begin{equation*}
f_{h_{+}} * f_{r_{0} r_{1}}=q f_{h_{+} r_{0} r_{1}} \tag{3.31}
\end{equation*}
$$

Similarly, for $h \in\left\{h_{+}, h_{-}\right\}$,

$$
\begin{align*}
& f_{h} * f_{r_{0} r_{1}}=q f_{h r_{0} r_{1}}=f_{r_{0} r_{1}} * f_{h}  \tag{3.32}\\
& f_{h} * f_{r_{1} r_{0}}=q f_{h r_{1} r_{0}}=f_{r_{1} r_{0}} * f_{h}
\end{align*}
$$

and

$$
\begin{align*}
& f_{h} * f_{r_{0}}=f_{h r_{0}}=f_{r_{0}} * f_{h}  \tag{3.33}\\
& f_{h} * f_{r_{1}}=q f_{h r_{1}}=f_{r_{1}} * f_{h} .
\end{align*}
$$

We are now ready to prove the proposition in general. Consider the case when $g=1$. Write $d$ as $h^{m}$, with $m \geqslant 0$ and $h \in\left\{h_{+}, h_{-}\right\}$. Write $w$ in the form
(i) $\left(r_{0} r_{1}\right)^{\prime} k, \quad s \geqslant 0$ and $k \in\left\{1, r_{0}\right\}$ or
(ii) $\left(r_{1} r_{0}\right)^{\prime} k, \quad s \geqslant 0$ and $k \in\left\{1, r_{1}\right\}$.

If $m \geqslant 1$ and $s \geqslant 1$, then
(i) $B h^{m} w B=B h\left(r_{0} r_{1}\right) B B h^{m-1}\left(r_{0} r_{1}\right)^{\prime-1} k B$, $w$ type (3.34i)
(ii) $B h^{m} w B=B h\left(r_{1} r_{0}\right) B B h^{m-1}\left(r_{1} r_{0}\right)^{)^{-1}} k B, \quad w$ type (3.34ii).

Thus, under these conditions,

$$
\begin{align*}
& \text { (i) } f_{h} m_{n}=f_{h\left(r_{0} r_{1}\right)} * f_{h^{m-1}\left(r_{0} r_{1}\right)^{1-1 /}} \\
& =q^{-1} f_{h} * f_{r_{0} r_{1}} * f_{h^{m-1}\left(r_{0} r_{1}\right)^{-1} h}  \tag{3.36}\\
& \text { (ii) } f_{h} m_{n}=f_{h\left(r_{1} r_{0}\right)} * f_{h^{m-1}\left(r_{1} r_{0}\right)^{-1} h} \\
& =q^{-1} f_{h} * f_{r_{1} r_{0}} * f_{h^{m-1}\left(r_{1} r_{0}\right)^{-1} k} .
\end{align*}
$$

That $f_{d}$ and $f_{n}$ commute and the formula for the convolution now follows by repeated applications of $(3.28,32,33,36)$. The proof in the case $g=t^{\prime}$ is more tedious but follows the same method. We omit the details.

Since $B t^{\prime} B t^{\prime} B=B h_{-} \varpi I B=B h_{-} B \varpi I B$, we have

$$
\begin{equation*}
f_{t^{\prime}} * f_{t^{\prime}}=f_{h_{-} \sigma I}=f_{h_{-}} * f_{\sigma I} \tag{3.37}
\end{equation*}
$$

The elements $f_{t^{\prime}}, f_{\sigma_{I}}, f_{r_{0}}$ and $f_{r_{1}}$ therefore generate $\mathscr{H}$. In order to determine the exact structure of $\mathscr{H}$, we need to compute the relations among $f_{t^{\prime}}, f_{w I}$, $f_{r_{0}}$ and $f_{r_{1}}$. We merely state the relations and omit the cumbersome but straightforward computations.

$$
\begin{align*}
& f_{t^{\prime}} * f_{t^{\prime-1}}=q^{2} f_{1} \\
& f_{r_{0}} * f_{r_{0}}=q f_{1}+(q-1) f_{r_{0}}  \tag{3.38}\\
& f_{t^{\prime}} * f_{r_{0}} * f_{t^{\prime-1}}=q f_{r_{1}}
\end{align*}
$$

Using the notation of (1.7), let $G^{\prime}$ be the group

$$
\begin{equation*}
G^{\prime}=\mathbf{M}_{\left\{\left\{_{0}\right\}\right.}(F) \tag{3.39}
\end{equation*}
$$

The group $W^{\prime}$ is the Weyl group of $G^{\prime}$. The group $B^{\prime}=G^{\prime} \cap B$ is an Iwahori subgroup of $G^{\prime}$. Let $e_{n}, w \in W^{\prime}$, be the characteristic function of $B^{\prime} W B^{\prime}$. Combining ( $3.28,29,37,38$ ), and Proposition 3.9 together, we get

Proposition 3.10. The map $\eta: \mathscr{H}^{\prime}\left(G^{\prime} \mid / B^{\prime}\right) \rightarrow \mathscr{H}(G / / B, \Omega)$ defined by

$$
\eta\left(e_{w}\right)=\left\{\operatorname{vol}(B w B) / \operatorname{vol}\left(B^{\prime} w B^{\prime}\right)\right\}^{-1 / 2} f_{w}, \quad w \in W^{\prime \prime}
$$

is $a *$-isomorphism of algebras.
The remark after Corollary 3.8 applies here: $G^{\prime} / T$ has no discrete series; hence, there are none of $G / T$ containing $\Omega^{t}$.

Case (iv) $\chi=\theta / \varphi \neq \operatorname{sgn}$ or 1 . The results in this case are parallel to those of case (iii). The proofs of the results in case (iv) follow the same pattern as in case (iii). As such, we merely state the results and omit the proofs. Let

$$
r_{0}=\varpi^{-1} E_{1,2}+\varpi E_{2,1}+\varpi^{-1} E_{3,4}+\varpi E_{4,3}=s_{2} s_{0} s_{1} s_{0} s_{2}
$$

$$
\begin{align*}
& r_{1}=s_{1} \\
& d_{+}, d_{-} \text {as in }(3.23)  \tag{3.40}\\
& t^{\prime}=E_{1,2}+\varpi E_{2,1}+E_{3,4}+\varpi E_{4,3}=s_{2} s_{0} t d(1,-1,-1) .
\end{align*}
$$

The group $W^{\prime}$ is the Weyl group of $G^{\prime}=\mathbf{M}_{\left\{s_{1}\right\}}(F)$, and $B^{\prime}=G^{\prime} \cap B$ is an Iwahori subgroup of $G^{\prime}$. Let $e_{w}$ again denote the characteristic function of $B^{\prime} w B^{\prime}$.

Proposition 3.11. The map $\eta: \mathscr{H}^{\prime}\left(G^{\prime} / / B^{\prime}\right) \rightarrow \mathscr{H}(G \| B, \Omega)$ defined by

$$
\eta\left(e_{w}\right)=\left\{\operatorname{vol}(B w B) / \operatorname{vol}\left(B^{\prime} w B^{\prime}\right)\right\}^{-1 / 2} f_{w}, \quad w \in W^{\prime}
$$

is $a^{*}$-isomorphism of algebras.

Again, $G^{\prime} / T$ has no discrete series and therefore, none of $G / T$ containing $\Omega^{t}$.

Case (v) $\chi=\theta / \varphi=\operatorname{sgn}$. Let

$$
\begin{align*}
& r_{0}=\varpi^{-1} E_{1,3}+\varpi^{-1} E_{2,4}+\varpi E_{3,1}+\varpi E_{4,2}=s_{2} s_{1} s_{2} d(1,1,-1) \\
& r_{1}=t^{-1} r_{0} t=s_{0} s_{1} s_{0} d(1,1,-1) \\
& r_{0}^{\prime}=\varpi^{-1} E_{1,2}+\varpi E_{2,1}+\varpi^{-1} E_{3,4}+\varpi E_{4,3}=s_{2} s_{0} s_{1} s_{0} s_{2}  \tag{3.41}\\
& r_{1}^{\prime}=s_{1} \\
& t^{\prime}=E_{1,2}+\varpi E_{2,1}+E_{3,4}+\varpi E_{4,3}=s_{2} s_{0} t d(1,-1,-1)
\end{align*}
$$

Set

$$
\begin{align*}
& W_{r}=\text { subgroup of } W^{\prime} \text { generated by } r_{0} \text { and } r_{1} \\
& W_{r}^{e}=\text { subgroup of } W^{\prime} \text { generated by } W_{r} \text { and } t  \tag{3.42}\\
& W_{r^{\prime}}=\text { subgroup of } W^{\prime} \text { generated by } r_{0}^{\prime} \text { and } r_{1}^{\prime} \\
& W_{r^{\prime}}^{e}=\text { subgroup of } W^{\prime} \text { generated by } W_{r^{\prime}} \text { and } t^{\prime}
\end{align*}
$$

Both $W_{r}$ and $W_{r^{\prime}}$ are infinite dihedral groups generated by two generators. The two groups $W_{r}^{e}$ and $W_{r^{\prime}}^{e}$ centralize one another and

$$
\begin{equation*}
W^{\prime}=W_{r}^{e} W_{r^{\prime}}^{e}, \quad W_{r}^{e} \cap W_{r^{\prime}}^{e}=\text { image of } T \text { in } W^{\mathrm{aff}} \tag{3.43}
\end{equation*}
$$

In particular, any element of $W^{\prime}$ can be written in the form $w w^{\prime}$, with $w \in W$ (resp. $w^{\prime} \in W^{\prime}$ ) and $w, w^{\prime}$ are unique modulo $T$. Let $\ell_{r}\left(\right.$ resp. $\left.\ell_{r}^{\prime}\right)$ be the length function in $W_{r}$ (resp. $W_{r^{\prime}}$ ). An easy verification shows

$$
\ell_{r}\left(w w^{\prime}\right)=\ell_{r}(w)+\ell_{r}\left(w^{\prime}\right) \text { iff } \ell\left(w w^{\prime}\right)=\ell(w)+\ell\left(w^{\prime}\right), \quad w, w^{\prime} \in W_{r}
$$

$$
\begin{equation*}
\ell_{r}^{\prime}\left(w w^{\prime}\right)=\ell_{r}^{\prime}(w)+\ell_{r}^{\prime}\left(w^{\prime}\right) \text { iff } \ell\left(w w^{\prime}\right) .=\ell(w)+\ell\left(w^{\prime}\right), \quad w, w^{\prime} \in W_{r^{\prime}} \tag{3.44}
\end{equation*}
$$

Hence, if both $w, w^{\prime} \in W_{r}\left(\right.$ resp. $\left.W_{r^{\prime}}\right)$, then

$$
\begin{equation*}
f_{w^{\prime}} * f_{w^{\prime}}=f_{w w^{\prime}} \tag{3.45}
\end{equation*}
$$

provided their $\ell_{r}$ (resp. $\ell_{r^{\prime}}$ ) lengths add.
Both $\ell_{r}$ and $\ell_{r}^{\prime}$ can be extended to $W_{r}^{e}$ and $W_{r^{\prime}}^{e}$. Indeed, set $\ell_{r}(w t)=\ell_{r}(w)$, $w \in W_{r}$, and set $\ell_{r}^{\prime}\left(w^{\prime} t^{\prime}\right)=\ell_{r}^{\prime}\left(w^{\prime}\right), w^{\prime} \in W_{r}^{\prime}$. It is clear that

$$
\begin{aligned}
& f_{n} * f_{t}=f_{w t}, \quad w \in W_{r} \\
& f_{t} * f_{t}=f_{w I}, \quad f_{t} * f_{t-1}=f_{1}
\end{aligned}
$$

and

$$
\begin{equation*}
f_{t} * f_{r_{1}} * f_{t^{-1}}=f_{r_{0}} \tag{3.46}
\end{equation*}
$$

Since

$$
B r_{1} B r_{1} B=B \cup B s_{0} B \cup B s_{0} s_{1} s_{0} B \cup B s_{1} s_{0} s_{1} B \cup B s_{0} s_{1} s_{0} s_{1} B
$$

the convolution $f_{r_{1}} * f_{r_{1}}$ is linear combination of $f_{1}, f_{r_{1}}$ and $f_{r_{1} r_{1}}$. We have

$$
\begin{equation*}
f_{r_{1}} * f_{r_{1}}(1)=\int_{G} f_{r_{1}}(g) f_{r_{1}}\left(g^{-1}\right) \mathrm{d} g=\operatorname{vol}\left(B r_{1} B\right)=q^{3} \tag{3.47}
\end{equation*}
$$

To evaluate $f_{r_{1}} * f_{r_{1}}\left(r_{1} r_{1}^{\prime}\right)$, we evaluate

$$
f_{r_{1}} * f_{r_{1}}\left(r_{1} r_{1}^{\prime}\right)=\int_{G} f_{r_{1}}(g) f_{r_{1}}\left(g^{\prime}\right) \mathrm{d} g, \quad \text { where } g g^{\prime}=r_{1} r_{1}^{\prime}
$$

The integrand is nonzero precisely when $g, g^{\prime}$ both belong to $B r_{1} B$. Write $g$ as

$$
g=u_{b}(D) u_{a+b}(E) u_{2 a+b}(C) r_{1} m, \quad C, D, E \in R, m \in B,
$$

and $g^{\prime}$ as

$$
g^{\prime}=m^{\prime} r_{1} u_{b}\left(D^{\prime}\right) u_{a+b}\left(E^{\prime}\right) u_{2 a+b}\left(C^{\prime}\right), \quad C^{\prime}, D^{\prime}, E^{\prime} \in R, m^{\prime} \in B
$$

Let $\nsim$ denote the prime ideal in $R$. Then, $g g^{\prime}=r_{1} r_{1}^{\prime}$ is equivalent to $E$, $E^{\prime} \in h, C C^{\prime}=D D^{\prime}=-1 \bmod h$. Thus,

$$
\begin{equation*}
f_{r_{1}} * f_{r_{1}}\left(r_{1} r_{1}^{\prime}\right)=\sum_{C, D \text { unts }} \chi\left(-C^{-1}\right) \theta\left(D^{-1}\right) \varphi(C)=0 . \tag{3.48}
\end{equation*}
$$

In a similar fashion

$$
\begin{align*}
f_{r_{1}} * f_{r_{1}}\left(r_{1}\right) & =\sum_{E \text { unnt }, C} \chi\left(-E^{-1}\right) \theta\left(-E^{-1}\right) \varphi(E)  \tag{3.49}\\
& =(q-1) q \chi(-1) \theta(-1) .
\end{align*}
$$

Set $\kappa=\chi(-1) \theta(-1)$, so $\kappa$ is $\pm 1$. Combining $(3.47,48,49)$ we obtain

$$
\begin{equation*}
f_{r_{1}} * f_{r_{1}}=q^{3} f_{1}+(q-1) q \kappa f_{r_{1}} . \tag{3.50}
\end{equation*}
$$

In particular, it follows that the vector space of functions

$$
\begin{equation*}
\mathscr{A}=\left\{f \in \mathscr{H} \mid \text { support of } f \subset B W_{r}^{e} B\right\} \tag{3.51}
\end{equation*}
$$

is a subalgebra of $\mathscr{H}(G / / B, \Omega)$. In order to identify $\mathscr{A}$, consider $G^{\prime \prime}=$ $\mathbf{G L} \mathbf{2}_{\mathbf{2}}(F)$. Let $B^{\prime \prime}$ be the Iwahori group of matrices in $\mathbf{G L}_{2}(R)$ which are upper triangular $\bmod h$. Let $A^{\prime \prime}$ be the diagonal matrices in $G^{\prime \prime}$ and let

$$
r_{0}^{\prime \prime}=\left[\begin{array}{cc}
0 & m^{-1}  \tag{3.52}\\
\pi & 0
\end{array}\right], \quad r_{1}^{\prime \prime}=\left[\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right] \text { and } t^{\prime \prime}=\left[\begin{array}{ll}
0 & 1 \\
\nabla & 0
\end{array}\right] .
$$

Let $N^{\prime \prime}=A^{\prime \prime} \cup t^{\prime \prime} A^{\prime \prime}$ be the monomial matrices, and $W^{\text {aff } \prime}=N /\{N \cap B\}$ the affine Weyl group of $G^{\prime \prime}$. Let $e_{w}$ be the characteristic function of $B^{\prime \prime} w B^{\prime \prime}$. Combining $(3.45,46,50)$ yields

Proposition 3.12. The map $\eta: \mathscr{H}\left(G^{\prime \prime}| | B^{\prime \prime}\right) \rightarrow \mathscr{A}$ defined by

$$
\eta\left(e_{r_{0}^{\prime \prime}}\right)=\{\kappa q\}^{-1} f_{r_{0}}, \quad \eta\left(e_{r_{1}^{\prime \prime}}\right)=\{\kappa q\}^{-1} f_{r_{1}} \quad \text { and } \quad \eta\left(e_{t^{\prime \prime}}\right)=f_{t}
$$

is $a^{*}$-isomorphism of algebras.
In a likewise manner, the vector space of functions

$$
\begin{equation*}
\mathscr{B}=\left\{f \in \mathscr{H} \mid \text { support of } f \subset B W_{r^{\prime}}^{e} B\right\} \tag{3.53}
\end{equation*}
$$

is a subalgebra of $\mathscr{H}(G / / B, \Omega)$, and
Proposition 3.13. Let $\kappa=\theta(-1)$. The map $\eta: \mathscr{H}\left(G^{\prime \prime} \| B^{\prime \prime}\right) \rightarrow \mathscr{B}$ defined by

$$
\eta\left(e_{r_{0}^{\prime \prime}}\right)=\left\{\kappa q^{2}\right\}^{-1} f_{r_{0}^{\prime}}, \quad \eta\left(e_{r_{1}^{\prime}}\right)=\kappa^{-1} f_{r_{1}^{\prime}} \text { and } \quad \eta\left(e_{t^{\prime \prime}}\right)=q^{-1} f_{t^{\prime}}
$$

is $a^{*}$-isomorphism of algebras.

The vector space

$$
\begin{equation*}
\mathscr{C}=\{f \in \mathscr{H} \mid \text { support of } f \subset B T A(R) B\} \tag{3.54}
\end{equation*}
$$

is contained in the center of $\mathscr{H}$ and also in $\mathscr{A}$ and $\mathscr{B}$. The next result identifies $\mathscr{H}$ as the tensor product $\mathscr{H}=\mathscr{A} \otimes_{6} \mathscr{B}$.

Proposition 3.14. For $w \in W_{r}^{e}, w^{\prime} \in W_{r^{\prime}}^{e} ; f_{w^{\prime}}$ and $f_{w^{\prime}}$ commute and

$$
q^{-\ell(w) / 2} f_{w} * q^{-\ell\left(w^{\prime}\right) / 2} f_{w^{\prime}}=q^{-\ell\left(w w^{\prime}\right) / 2} f_{w w^{\prime}}
$$

Proof. The method of proof is basically the same as the one used in Proposition 3.9. Let

$$
\begin{align*}
& d_{+}, d_{-} \text {as in (3.23) }  \tag{3.55}\\
& g_{+}=\varpi^{-1} E_{1,1}+E_{2,2}+\varpi^{-1} E_{3,3}+E_{4,4} \quad \text { and } \quad g_{-}=g_{+}^{-1}
\end{align*}
$$

Modulo $T$, an element $w \in W_{r}^{e}$ is one of two forms:
(i) $\varpi^{a} I d^{m}$ or
(ii) $\varpi^{a} I d^{m} t, \quad m \geqslant 0, d \in\left\{d_{+}, d_{-}\right\}$

Similarly, an element $w^{\prime} \in W_{r^{\prime}}^{e}$ is of the form

$$
\begin{equation*}
\text { (i) } \varpi^{b} I g^{n} \text { or (ii) } \varpi^{b} I g^{n} t^{\prime}, \quad n \geqslant 0, \quad g=\left\{g_{+}, g_{-}\right\} \text {. } \tag{3.57}
\end{equation*}
$$

Consider $w$ of type (3.56i) and $w^{\prime}$ of type (3.57(i)). If either $m$ or $n$ is zero the result is trivial. If $m \geqslant 1$ and $n \geqslant 1$, then

$$
B \varpi^{a} I d^{m} \varpi^{b} I g^{n} B=\{B \varpi I B\}^{a+b}\{B d g B\}\left\{B d^{m-1} g^{n-1} B\right\},
$$

so

$$
f_{\nabla^{a} I d^{m}} * f_{\nabla^{b} I g^{n}}=\left(f_{\sigma I}\right)^{a+b} * f_{d h} * f_{d^{m-1} g^{n-1}}
$$

Hence, the proposition will follow for $w$ of type (3.56i) and $w^{\prime}$ of type (3.57i) provided

$$
f_{d} * f_{g}=q f_{d g}
$$

This last relation is proved by the same method used to show (3.50). The proof of the proposition for the other three cases of $w$ and $w^{\prime}$ is similar. We omit the details.

There are four square integrable representations of $G / T$ which contain $\Omega^{\prime}$. They correspond to the one dimensional representations $\pi$ of $\mathscr{H}$ given by

$$
\begin{align*}
& \pi\left(f_{r}\right)=-1, \quad r \in\left\{r_{0}, r_{1}, r_{0}^{\prime}, r_{1}^{\prime}\right\}  \tag{3.58}\\
& \pi\left(f_{t}\right)= \pm 1 \quad \text { and } \quad \pi\left(f_{t^{\prime}}\right)= \pm 1
\end{align*}
$$

These representations have formal degree

$$
\begin{equation*}
\{(q-1) /\{2(q+1)\}\}^{2} / \operatorname{vol}(B) . \tag{3.59}
\end{equation*}
$$

Case $P=P_{\left\{s_{0}\right\}}$. Here, in the notation of (1.7), we have

$$
\begin{align*}
P / P_{1} & =\mathbf{M}_{\left\{\left\{_{0}\right\}\right.}\left(\mathbb{F}_{q}\right)  \tag{3.60}\\
& =\left\{\left.\left[\begin{array}{lll}
a & & \\
& A & \\
& & d
\end{array}\right] \right\rvert\, A \in \mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) \quad \text { and } \quad \operatorname{det} A=a d\right\} .
\end{align*}
$$

A cuspidal representation of $P / P_{1}$ is a tensor product $\Omega=\xi \otimes \sigma$, where $\xi$ is a character of $\mathbb{E}_{q}^{\times}$, i.e., the $a$ component, and $\sigma$ is a cuspidal representation of $\mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right)$, the $A$ component. Representatives $w$ for the double cosets $P w P$ which can be in the support of $\mathscr{H}=\mathscr{H}(G / / P, \Omega)$ have the form

$$
\begin{align*}
& \varpi^{m}\left\{\varpi^{-r} E_{1,1}+E_{2,2}+E_{3,3}+\varpi^{r} E_{4,4}\right\} \text { or }  \tag{3.61a}\\
& \varpi^{m}\left\{(-\varpi)^{-r} E_{1,4}+E_{2,2}+E_{3,3}+-(-\varpi)^{r} E_{4,1}\right\} \tag{3.61b}
\end{align*}
$$

with $m, r \in \mathbb{Z}$. We have selected a slightly complicated form for (3.61b) in order that the representatives (3.61a, b) satisfy (3.6). The elements (3.61a) always belong to supp $\mathscr{H}$ for any pair ( $\xi, \sigma$ ). On the other hand, elements (3.61b) lie in supp $\mathscr{H}$ precisely when
(i) $\xi$ is the trivial character and $\sigma$ is any cuspidal representation
(ii) $\xi$ is the character of order 2 and $\sigma$ is a cuspidal representation such that $\sigma$ is equivalent to $\sigma \otimes(\xi \circ \operatorname{det})$.

Up to scalar multiple, each $w \in \operatorname{supp} \mathscr{H}$ determines a function $f_{w}$ whose support is precisely $P w P$. The set of $f_{w}$ 's is a basis for $\mathscr{H}$. If $w, w^{\prime} \in \operatorname{supp} \mathscr{H}$, and $P w P w^{\prime} P=P w w^{\prime} P$, then by Proposition 2.2 in [HM1],

$$
\begin{equation*}
f_{w} * f_{w^{\prime}}=\text { multiple of } f_{w w^{\prime}} . \tag{3.63}
\end{equation*}
$$

It shall be convenient to pick the $f_{w}$,s so that (3.63) holds with the scalar equal to 1 . For $w$ an element of the form (3.61a), let $f_{w}$ be the function in $\mathscr{H}$, with support $P w P$ and

$$
\begin{equation*}
f_{w}(w)=\text { identity operator. } \tag{3.64a}
\end{equation*}
$$

To describe the function $f_{w}$, when $w$ is of the form (3.61b), we treat separately the cases (3.62i) and (3.62ii).

Case (3.62(i)). Here, let $f_{w}$ be the function with support $P w P$ and

$$
\begin{equation*}
f_{w}(w)=\text { identity operator. } \tag{3.64b}
\end{equation*}
$$

Case (3.62(ii)). In order to describe $f_{w}$, we need to introduce some preliminary notation. Let $V_{\sigma}$ be the representation space of $\sigma$. The restriction of $\sigma$ to $\mathbf{S L}_{2}\left(\mathbb{F}_{q}\right)$ decomposes into two irreducible components of degree $(q-1) / 2$ each. The two representations are distinguished by their character values on
the two non-identity unipotent conjugacy classes in $\mathbf{S L}_{2}\left(\mathbb{F}_{q}\right)$. Let

$$
u_{+}=\left[\begin{array}{ll}
1 & 1 \\
0 & 1
\end{array}\right] \quad u_{-}=\left[\begin{array}{ll}
1 & \varepsilon \\
0 & 1
\end{array}\right]
$$

and let

$$
\begin{aligned}
& \gamma_{+}=\left\{-1+\sqrt{ }\left\{(-1)^{(q-1) / 2} q\right\}\right\} \\
& \gamma_{-}=\left\{-1-\sqrt{ }\left\{(-1)^{(q-1) / 2} q\right\}\right\} .
\end{aligned}
$$

Then

$$
\begin{aligned}
& V_{\sigma}=V_{+} \oplus V_{-} \\
& \sigma=\sigma_{+} \oplus \sigma_{-}
\end{aligned}
$$

where

$$
\begin{array}{ll}
\operatorname{trace} \sigma_{+}\left(u_{+}\right)=\gamma_{+} & \operatorname{trace} \sigma_{+}\left(u_{-}\right)=\gamma_{-}  \tag{3.65}\\
\operatorname{trace} \sigma_{-}\left(u_{+}\right)=\gamma_{-} & \text {trace } \sigma_{-}\left(u_{-}\right)=\gamma_{+}
\end{array}
$$

Define $J$ to be the element in End $V_{\sigma}$ which is the identity on $V_{+}$and minus the identity on $V_{-}$. Then

$$
\begin{equation*}
J \sigma(k) \xi(\operatorname{det}(k))=\sigma(k) J \quad \text { for } \quad k \in \mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) . \tag{3.66}
\end{equation*}
$$

We have now developed enough notation to describe $f_{w}$. For $w$ of the form (3.61b), let $f_{w}$ be the function in $\mathscr{H}$ with support $P w P$ and

$$
\begin{equation*}
f_{w}(w)=J \tag{3.64c}
\end{equation*}
$$

The $f_{w}$ 's in (3.64a, b, c) have been defined so that

$$
f_{w} * f_{w^{\prime}}=f_{w w^{\prime}} \quad \text { whenever } \quad P w P w^{\prime} P=P w w^{\prime} P
$$

We now describe the structure of $\mathscr{H}$ according to whether the elements of $W^{\text {aff }}$ in supp $\mathscr{H}$ have the form (3.61a) or (3.61a, b).

Case 1. supp $\mathscr{H}=\{P w P \mid w$ of the form (3.61a) $\}$. Let $h_{+}$and $h_{-}$be as in (3.23). Every element $w$ of the form (3.61a) is uniquely a nonnegative power of $h_{+}$or $h_{-}$times a scalar matrix $\varpi^{m} I$. Let $W^{\prime}$ be the subgroup of $N$ generated by $h_{+}$, and $\varpi I$. Then,

```
supp \mathscr{H}=P\mp@subsup{W}{}{\prime}P.
```

Write $w$ as $\varpi^{m} h^{s}$ with $m$ an integer, $h \in\left\{h_{+}, h_{-}\right\}$and $s$ a nonnegative integer. Then, since

$$
P w P=P \varpi^{m} I P\{P h P\}^{s},
$$

we have, $f_{w}=\left(f_{w I}\right)^{m} *\left(f_{h}\right)^{s}$. If $w^{\prime}=\varpi^{m^{\prime}} h^{s^{\prime}}$ and $h^{\prime}=h$, then $P s P w^{\prime} P=$ $P w w^{\prime} P=P w^{\prime} P w P$ and so $f_{w} * f_{w^{\prime}}=f_{w w^{\prime}}=f_{w^{\prime}} * f_{w}$. Suppose now $h \neq h^{\prime}$. The next result determines the product between $h_{+}$and $h_{-}$and hence between $f_{w}$ and $f_{w^{\prime}}$.

Proposition 3.5. $f_{h_{+}} * f_{h_{-}}=q^{4} f_{I}=f_{h_{-}} * f_{h_{+}}$.
Proof. The support of $f_{h_{+}} * f_{h_{-}}$is shown to be $P$ by the same reasoning as in Proposition 3.5. We conclude that $f_{h_{+}} * f_{h_{-}}$is a multiple of $f_{I}$. The multiple is easily seen to be $q^{4}=\left[P d_{+} P: P\right]$.

Let $G^{\prime}$ denote the group

$$
\begin{equation*}
G^{\prime}=\{g \in \mathbf{A}(F) \mid(2,2) \text { and }(3,3) \text { entries are equal }\} \tag{3.67}
\end{equation*}
$$

and let $P^{\prime}=G^{\prime} \cap P$. In this setup, supp $\mathscr{H}=P G^{\prime} P$, and the Hecke algebra $\mathscr{H}\left(G^{\prime} / / P^{\prime}\right)$ is the group algebra of $G^{\prime} / P^{\prime}$. Each double coset of $P^{\prime}$ in $G^{\prime}$ is represented by an element $w$ of the form (3.61a). Let $e_{w}$ be the characteristic function of $w P^{\prime}$, and let $r$ be as in (3.61a). Then,

Corollary 3.16. The map $\eta: \mathscr{H}\left(G^{\prime} / / P^{\prime}\right) \rightarrow \mathscr{H}(G / / P, \Omega)$ defined by

$$
\eta\left(e_{w}\right)=q^{-2|r|} f_{w}
$$

is $a^{*}$-isomorphism of algebras.
As in the previous cases, $\eta$ determines a transfer between the characters of $G^{\prime} / P^{\prime}$ (resp. $\left\{G^{\prime} / T\right\} /\left\{T P^{\prime} / T\right\}$ ) and the irreducible representations of $G$ (resp. $G / T)$ which contain $\Omega^{t}$. There are no square integrabl representations of $G / T$ containing $\Omega^{t}$.

Case 2. supp $\mathscr{H}=\{P w P \mid w$ of the form (3.61a, b) $\}$. Let

$$
\begin{equation*}
r_{0}=E_{1,4}+E_{2,2}+E_{3,3}-E_{4,1}=s_{1} s_{0} s_{1} \quad \text { and } \quad r_{1}=s_{2} \tag{3.68}
\end{equation*}
$$

The subgroup of $W^{\text {aff }}$ generated by $r_{0}$ and $r_{1}$ is an infinite dihedral group. Let

$$
\begin{equation*}
W^{\prime}=\left\langle r_{0}, r_{1}, \varpi I\right\rangle \tag{3.69}
\end{equation*}
$$

be the subgroup of $W^{\text {aff }}$ generated by $r_{0}, r_{1}$ and $\varpi I$. The support of $\mathscr{H}$ is equal to $P W^{\prime} P$. We need to determine the multiplication between the $f_{n}$ 's. Let $\ell^{\prime}$ be the length function in $W^{\prime}$.

Lemma 3.17. For $w, w^{\prime}$ as in (3.61a, b$)$, the following are equivalent
(i) $\ell\left(w w^{\prime}\right)=\ell(w)+\ell\left(w^{\prime}\right)$
(ii) $\ell^{\prime}\left(w w^{\prime}\right)=\ell^{\prime}(w)+\ell^{\prime}\left(w^{\prime}\right)$
(iii) $P w w^{\prime} P=P w P w^{\prime} P$.

Proof. The element (3.61a) is equal to $\varpi^{m} h_{+}^{r}$ if $r \geqslant 0$ and $\varpi^{m} h_{-}^{-r}$ if $r<0$, while the element (3.61b) is equal to $\varpi^{m} h_{+}^{r-1} r_{1}$ if $r \geqslant 1$ and $\varpi^{m} h_{-}^{-r} r_{0}$ if $r \leqslant 0$. Lable these four cases type I, II, III and IV respectively. If $w$ is type I or type IV, then each of the three relations (i), (ii) and (iii) holds precisely when $w^{\prime}$ is type I or type III respectively. When $w$ is type II or type III, each of the three relations holds exactly when $w^{\prime}$ is respectively type II or type IV.

Let $\kappa$ be the scalar $\sigma(-1)$. The next result determines the structure of $\mathscr{H}$.
Theorem 3.18. The elements $f_{w}$ satisfy
(a) $f_{w^{\prime}} * f_{w^{\prime}}=f_{w x^{\prime}}$ for $\ell^{\prime}\left(w w^{\prime}\right)=\ell^{\prime}(w)+\ell^{\prime}\left(w^{\prime}\right)$
(b) (i) for $\Omega$ as (3.62i)

$$
\begin{aligned}
& f_{r_{1}} * f_{r_{1}}=q f_{1}+(q-1) f_{r_{1}} \\
& f_{r_{0}} * f_{r_{0}}=q^{3} f_{1}-(q-1) q \kappa f_{r_{0}}
\end{aligned}
$$

(b) (ii) for $\Omega$ as (3.62ii)

$$
\begin{aligned}
& f_{r_{1}} * f_{r_{1}}=q \xi(-1) f_{1} \\
& f_{r_{0}} * f_{r_{0}}=q^{3} \xi(-1) f_{1}+\left(q^{2}-1\right)\left(\gamma-\gamma^{\prime}\right) \kappa f_{r_{0}}
\end{aligned}
$$

Proof. Relation (a) is a consequence of Lemma 3.17 and Proposition 2.2 in [HM1]. To show relation (b) we begin by determining the support of $f_{r_{1}} * f_{r_{1}}$ and $f_{r_{0}} * f_{r_{0}}$. The support of $f_{r_{1}} * f_{r_{1}}$ is contained in the set $\operatorname{Pr}_{1} P r_{1} P$. Observe, as in the proof of Proposition 3.4, that

$$
\operatorname{Pr}_{1} P r_{1} P=P s_{2}\left(B \cup B s_{0} B\right) s_{2} P=P s_{2} P \cup P \cup P s_{2} s_{0} P \cup P s_{0} P=P \cup P s_{2} P
$$

This means $f_{r_{1}} * f_{r_{1}}$ is a linear combination of $f_{1}$ and $f_{r_{1}}$. Similarly, the support of $f_{r_{0}} * f_{r_{0}}$ is contained in the set $\operatorname{Pr}_{0} P r_{0} P$ and

$$
P r_{0} P r_{0} P=P \cup P s_{1} P \cup P s_{1} s_{0} s_{1} P
$$

But $P s_{1} P$ is not in the support of $\Omega$. The convolution $f_{r_{0}} * f_{r_{0}}$ is therefore, a linear combination of $f_{1}$ and $f_{r_{0}}$. So, $f_{r} * f_{r}, r \in\left\{r_{0}, r_{1}\right\}$, is a linear combination of $f_{1}$ and $f_{r}$. To determine the precise linear combination, we evaluate $f_{r} * f_{r}$ at 1 and $r$. The value of $f_{r} * f_{r}$ at 1 is

$$
\begin{aligned}
f_{r} * f_{r}(1) & =\int_{G} f_{r}(g) f_{r}\left(g^{-1}\right) \mathrm{d} g \\
& =\operatorname{vol}(\operatorname{Pr} P) \int_{P} \int_{P} f_{r}(x r y) f_{r}\left(y^{-1} r^{-1} x^{-1}\right) \mathrm{d} y \mathrm{~d} x \\
& =\operatorname{vol}(\operatorname{Pr} P) \xi(-1) .
\end{aligned}
$$

For $f_{r} * f_{r}(r)$, we have

$$
\begin{equation*}
f_{r} * f_{\mathrm{r}}(r)=\int_{G} f_{r}(g) f_{r}\left(g^{\prime}\right) \mathrm{d} g, \quad g g^{\prime}=r \tag{3.70}
\end{equation*}
$$

In order to evaluate $f_{r} * f_{r}(r)$ we use the sharp form of the Bruhat decomposition (3.20). We treat separately the two cases $r=r_{1}$ and $r=r_{0}$. The double coset $\operatorname{Pr}_{1} P$ has the product decomposition

$$
\begin{align*}
\operatorname{Pr}_{1} P & =U_{-2 a-b, 1} H_{1} r_{1} U_{-2 a-b, 1}  \tag{3.71}\\
& =U_{-2 a-b, 1} r_{1} H_{1} U_{-2 a-b, 1}
\end{align*}
$$

where $H_{1}$ is the set

$$
H_{1}=M_{\{s, 0} U_{a, 0} U_{a+b, 0} U_{-a, 1} U_{-a-b, 1}
$$

For $r_{0}$, we set

$$
H_{0}=M_{\left\{s_{0}\right\}}
$$

Then we have

$$
\begin{align*}
\operatorname{Pr}_{0} P & =U_{2 a+b, 0} U_{a+b, 0} U_{a, 0} H_{0} r_{0} U_{2 a+b, 0} U_{a+b, 0} U_{a, 0}  \tag{3.72}\\
& =U_{2 a+b, 0} U_{a+b, 0} U_{a, 0} r_{0} H_{0} U_{2 a+b, 0} U_{a+b, 0} U_{a, 0}
\end{align*}
$$

We use (3.71) and (3.72) to evaluate (3.70).

Case $r_{1}$. In (3.70), we write $g$ and $g^{\prime}$ as

$$
\begin{aligned}
g & =u_{-2 a-b}(\varpi x) r_{1} h_{1} u_{-2 a-b}(\varpi y) \\
g^{\prime} & =u_{-2 a-b}\left(\varpi y^{\prime}\right) h_{1}^{\prime} r_{1} u_{-2 a-b}(\varpi z)
\end{aligned}
$$

The product $g g^{\prime}$ is equal to $r_{1}$ precisely when $z$ is a unit, say $D, x=D^{-1}$ and

$$
h_{1} u_{-2 a-b}\left(\varpi\left(y+y^{\prime}\right)\right) h_{1}^{\prime}=d\left(D^{-1}, 1,1\right) u_{-2 a-b}\left(\varpi D^{-1}\right)
$$

Hence,

$$
\begin{aligned}
f_{r_{1}} * f_{r_{1}}\left(r_{1}\right) & =\operatorname{vol}\left(\operatorname{Pr}_{1} P\right) q^{-1} \sum_{D} f_{r_{1}}\left(r_{1}\right) \xi(D) f_{r_{1}}\left(r_{1}\right) \\
& =\left\{\begin{array}{cl}
(q-1) I & \text { if } \Omega \text { is of type (3.62i) } \\
0 & \text { if } \Omega \text { is of type (3.62ii) }
\end{array}\right.
\end{aligned}
$$

Case $r_{0}$. Here, we write $g$ and $g^{\prime}$ as

$$
\begin{aligned}
g & =\left[\begin{array}{cccc}
1 & x & y & z \\
0 & 1 & 0 & y \\
0 & 0 & 1 & -x \\
0 & 0 & 0 & 1
\end{array}\right] r_{0} m_{0} h_{0} \\
g^{\prime} & =h_{0}^{\prime} m_{0}^{\prime} r_{0}\left[\begin{array}{cccc}
1 & X & Y & Z \\
0 & 1 & 0 & Y \\
0 & 0 & 1 & -X \\
0 & 0 & 0 & 1
\end{array}\right]
\end{aligned}
$$

The product $g g^{\prime}$ is equal to $r_{0}$ precisely when $z$ is a unit $D, Z=D^{-1}$, $x=X D, y=Y D$, and
$m_{0} h_{0} h_{0}^{\prime} m_{0}^{\prime}=\left[\begin{array}{cccc}D^{-1} & 0 & 0 & 0 \\ 0 & 1-X Y D & -Y^{2} D & 0 \\ 0 & X^{2} D & 1+X Y D & 0 \\ 0 & 0 & 0 & D\end{array}\right]\left[\begin{array}{cccc}1 & X D & Y D & -D \\ 0 & 1 & 0 & Y D \\ 0 & 0 & 1 & -X D \\ 0 & 0 & 0 & 1\end{array}\right]$.

Let

$$
\left.u=\left[\begin{array}{cc}
1-X Y D & -Y^{2} D \\
X^{2} D & 1+X Y D
\end{array}\right] \text { (a unipotent element }\right) .
$$

Then,

$$
\begin{align*}
f_{r_{0}} * f_{r_{0}}\left(r_{0}\right) & =\operatorname{vol}\left(\operatorname{Pr}_{0} P\right) q^{-3} \sum^{\prime} f_{r_{1}}\left(r_{1}\right) \xi\left(D^{-1}\right) \sigma(u) f_{r_{1}}\left(r_{1}\right)  \tag{3.73}\\
& =\operatorname{vol}\left(\operatorname{Pr}_{0} P\right) q^{-3} \sum^{\prime} \xi\left(D^{-1}\right) \sigma(u)
\end{align*}
$$

The sum is over $X, Y \in R \bmod \nless$ and $D$ a unit $\bmod \nless$. Let $\chi_{\sigma}$ denote the character of $\sigma$. If $\Omega$ is of the form (3.62(i)), then taking the trace of both sides of (3.73) gives

$$
\operatorname{trace} f_{r_{0}} * f_{r_{0}}\left(r_{0}\right)=\sum^{\prime} \chi_{\sigma}(u)
$$

The character value $\chi_{\sigma}(u)$ is $(q-1) \kappa$ when $X$ and $Y$ are zero and $-\kappa$ otherwise. Hence, trace $\left(f_{r_{0}} * f_{r_{0}}\left(r_{0}\right)\right)=-\kappa(q-1)^{2} q$, and so

$$
f_{r_{0}} * f_{r_{0}}=q^{3} f_{1}-(q-1) q \kappa f_{r_{0}}
$$

If $\Omega$ is of the form (3.62(ii)), we can trace the two sides of (3.73) and use the explicit character values (3.65) to obtain

$$
f_{r_{0}} * f_{r_{0}}=q^{3} \xi(-1) f_{1}+\left(q^{2}-1\right)\left(\gamma-\gamma^{\prime}\right) \kappa f_{r_{0}}
$$

A consequence of Theorem 3.18 is that for $\Omega$ of type (3.62i), there is a Hecke algebra isomorphism of $\mathscr{H}=\mathscr{H}(G / / P, \Omega)$ in analogy with Propositions 3.2, 3.3, 3.10, 3.11 and Corollary 3.8. Let $G^{\prime}$ denote the group

$$
\begin{align*}
G^{\prime} & =\left\{\left[\begin{array}{llll}
a & 0 & 0 & b \\
0 & x & 0 & 0 \\
0 & 0 & x & 0 \\
c & 0 & 0 & d
\end{array}\right] \in G\right\},  \tag{3.74}\\
B^{\prime} & =G^{\prime} \cap P=\text { an Iwahori subgroup of } G^{\prime} .
\end{align*}
$$

The group $W^{\prime}$ of (3.69) is the affine Weyl group of $G^{\prime}$. Let $e_{w}, w \in W^{\prime}$, be the characteristic function of $B^{\prime} w B^{\prime}$.

Corollary 3.19. For $\Omega$ of type (3.62i), the map $\eta: \mathscr{H}\left(G^{\prime} / / B^{\prime}\right) \rightarrow \mathscr{H}(G / / P, \Omega)$ defined on generators by

$$
\eta\left(e_{\sigma I}\right)=f_{\varpi I}, \quad \eta\left(e_{r_{0}}\right)=(-q \kappa)^{-1} f_{r_{0}}, \quad \eta\left(e_{r_{1}}\right)=f_{r_{1}}
$$

is $a^{*}$-isomorphism of algebras.
It is now easy to describe the square integrable representations of $G / T$ which contain $\Omega^{\prime}$. There is one such representation $\tau$. It corresponds to the special representation $\tau_{S t}$ of $G^{\prime}$. The Hecke algebra representation is one dimensional and given by

$$
\begin{equation*}
\tau\left(e_{\pi I}\right)=1, \quad \tau\left(e_{r_{0}}\right)=-1 \quad \text { and } \quad \tau\left(e_{r_{1}}\right)=-1 . \tag{3.75}
\end{equation*}
$$

The formal degree $d_{\tau}$ of $\tau$ is

$$
\begin{equation*}
d_{\tau}=\{\operatorname{deg}(\Omega) / \operatorname{vol}(P)\}\left\{d_{S t} \operatorname{vol}\left(B^{\prime}\right)\right\}=(q-1)^{2} /\{(q+1) \operatorname{vol}(P)\} \tag{3.76}
\end{equation*}
$$

If $\Omega$ is type (3.62(ii)), there are two discrete series representations of $G / T$ containing $\Omega^{\prime}$. The corresponding representations of $\mathscr{H}$ are

$$
\begin{equation*}
\tau\left(f_{\text {wI }}\right)=1, \quad \tau\left(f_{r_{0}}\right)=-\left(\gamma-\gamma^{\prime}\right) \kappa \quad \text { and } \quad \tau\left(f_{r_{1}}\right)= \pm\left(\gamma-\gamma^{\prime}\right) \tag{3.77}
\end{equation*}
$$

The two representations have formal degree

$$
\begin{equation*}
d_{\tau}=\left\{(q-1)\left(q^{2}-1\right)\right\} /\left\{2\left(q^{2}+1\right) \operatorname{vol}(P)\right\} \tag{3.78}
\end{equation*}
$$

Case $P=P_{\left\{s_{1}\right\}}$. This case is very similar to the previous case $P=P_{\left\{s_{0}\right\}}$. We merely state the results and outline the proofs. Let

$$
J=\left[\begin{array}{ll}
0 & 1  \tag{3.79}\\
1 & 0
\end{array}\right]
$$

For $A \in \mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right)$, let $A^{\prime}$ be the transpose of $A$. In the notation of (1.7), we have

$$
\begin{align*}
P / P_{1} & =\mathbf{M}_{\{, 1\}}\left(\mathbb{F}_{q}\right) \\
& =\left\{\left.\left[\begin{array}{cc}
A & \\
& B
\end{array}\right] \right\rvert\, A \in \mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right), \quad \lambda \in \mathbb{F}_{q}^{\times} \quad \text { and } \quad B=\lambda J^{-1}\left(A^{t}\right)^{-1} J\right\} \tag{3.80}
\end{align*}
$$

A cuspidal representation of $P / P_{1}$ is a tensor product $\Omega=\xi \otimes \sigma$ where $\xi$ is a character $\mathbb{F}_{q}^{\times}$and $\sigma$ is a cuspidal representation of $\mathbf{G L}_{2}\left(\mathbb{F}_{q}\right)$. The elements of $W^{\text {aff }}$ which can belong to the support of $\mathscr{H}=\mathscr{H}(G / / P, \Omega)$ have the form

$$
\begin{align*}
& \varpi^{m}\left\{\varpi^{r} E_{1,1}+\varpi^{r} E_{2,2}+E_{3,3}+E_{4,4}\right\} \quad \text { or }  \tag{3.81a}\\
& \varpi^{m}\left\{E_{1,3}+E_{2,4}+\varpi^{r} E_{3,1}+\varpi^{r} E_{4,2}\right\} \tag{3.61b}
\end{align*}
$$

$m, r \in \mathbb{Z}$. Let $\theta$ denote the automorphism of $\mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right)$ of inverse transpose. Elements of type (3.81a) are always in supp $\mathscr{H}$, while those of type (3.81b) belong to supp $\mathscr{H}$ precisely when

$$
\begin{equation*}
\sigma \text { is a cuspidal representation of } \mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) \text { equivalent to } \sigma \circ \theta . \tag{3.82}
\end{equation*}
$$

Let $V_{\sigma}$ be the representation space of $\sigma$ and let

$$
\jmath=\sum \sigma(X)
$$

be the sum over those $2 \times 2$ invertible matrices $X$ whose $(1,1)$ and $(2,2)$ entries are equal. We have

$$
J^{2}=q^{2}(q-1)^{2} I
$$

and

$$
J \sigma(J \theta(k) J)=\sigma(k) J \quad \text { for } \quad k \in \mathbf{G L}_{\mathbf{2}}\left(\mathbb{F}_{q}\right) .
$$

We now describe the structure of $\mathscr{H}$ according to whether the elements of $W^{\text {aff }}$ in supp $\mathscr{H}$ have the form (3.81a) or (3.81a, b).

Case 1. supp $\mathscr{H}=\{P w P \mid w$ of the form (3.81a) $\}$. Set

$$
\begin{equation*}
d_{+}, d_{-} \text {as in (3.23) } \tag{3.83}
\end{equation*}
$$

Let $W^{\prime}$ be the subgroup of $W^{\text {aff }}$ generated by $d_{+}$and $\varpi I$, and let $G^{\prime}$ denote the group

$$
\begin{equation*}
G^{\prime}=\{g \in \mathbf{A}(F) \mid(1,1) \text { and }(2,2) \text { entries are equal }\} . \tag{3.84}
\end{equation*}
$$

Then,

$$
\operatorname{supp} \mathscr{H}=P W^{\prime} P=P G^{\prime} P
$$

Let $P^{\prime}=G^{\prime} \cap P$. The Hecke algebra $\mathscr{H}^{\prime}=\mathscr{H}\left(G^{\prime} / / P^{\prime}\right)$ is the group algebra of $G^{\prime} / P^{\prime}$. Each double coset of $P^{\prime}$ in $G^{\prime}$ is represented by an element $w$ of the form (3.81a). Let $f_{w^{\prime}}$ (resp. $e_{n}$ ) be the element in $\mathscr{H}^{(r e s p .} \mathscr{H}^{\prime}$ ) with support $P w P$ (resp. $w P^{\prime}$ ) and value the identity operator (resp. one) at $w$. Let $r$ be as in (3.81a). Then, in complete analogy with Proposition 3.15 and Corollary 3.16, we have

PROPOSITION 3.20. $f_{d_{+}} * f_{d_{-}}=q^{3} f_{I}=f_{d_{-}} * f_{d_{+}}$and

Corollary 3.21. The map $\eta: \mathscr{H}\left(G^{\prime} \mid / P^{\prime}\right) \rightarrow \mathscr{H}(G / / P, \Omega)$ defined by

$$
\eta\left(e_{n}\right)=q^{-3|r| / 2} f_{n}
$$

is $a^{*}$-isomorphism of algebras.

There are no discrete series representations of $G$ containing $\Omega^{\prime}$.

Case 2. supp $\mathscr{H}=\{P w P \mid w$ of the form (3.81a, b) $\}$. Take

$$
\begin{equation*}
r_{0}, r_{1} \text { and } t \text { as in (3.41). } \tag{3.85}
\end{equation*}
$$

Let $W^{\prime}$ be the subgroup of $W^{\text {aff }}$ generated by $r_{0}, r_{1}$ and $t$. The element $t$ conjugates $r_{0}$ to $r_{1}$. The subgroup $W_{d}$ of $W^{\prime}$ generated by $r_{0}$ and $r_{1}$ is again an infinite dihedral group. The support of $\mathscr{H}$ is equal to $P W^{\prime} P$. As in case 1, we exhibit a basis for $\mathscr{H}$. Let $f_{w}, w \in W^{\prime}$, be the function in $\mathscr{H}$ with support $P w P$ and

$$
f_{n}(w)=\left\{\begin{array}{l}
\text { identity operator, } w \text { type (3.81a) } \\
\{q(q-1)\}^{-1} \mathcal{J}, w \text { type (3.81b). }
\end{array}\right.
$$

The $f_{w}$ 's are a basis for $\mathscr{H}$. To determine the multiplication between the $f_{n}$ 's, let $\ell^{\prime}$ be the length function in $W^{\prime}$. Lemma 3.17 is valid in our present context. In analogy with Theorem 3.18, we have

Theorem 3.22. The elements $f_{n}$ satisfy
(a) $f_{n} * f_{w^{\prime}}=f_{\mathfrak{w w}^{\prime}}$ when $\ell^{\prime}\left(w w^{\prime}\right)=\ell^{\prime}(w)+\ell^{\prime}\left(w^{\prime}\right)$
(b) $f_{r_{1}} * f_{r_{1}}=q^{3} f_{1}+(q-1) q f_{r_{1}}$ $f_{t} * f_{r_{1}} * f_{t-1}=f_{r_{0}}$

There are two discrete series representations of $G / T$ containing $\sigma^{\prime}$. The corresponding representations $\pi$ of $\mathscr{H}$ are both one dimensional. They are given by

$$
\begin{equation*}
\pi\left(f_{r_{1}}\right)=-q, \quad \text { and } \quad \pi\left(f_{t}\right)= \pm 1 \tag{3.86}
\end{equation*}
$$

The formal degree of these two representations are

$$
\begin{equation*}
d_{\pi}=\{(q-1) /(2(q+1))\} \operatorname{vol}(P)^{-1} . \tag{3.87}
\end{equation*}
$$

This completes our analysis of the representations of $G$ which contain a level one nondegenerate representation. In Part II we give a classification of those representations of $G$ which contain a nondegenerate representation of higher level.

## Acknowledgements

It is a pleasure for the author to thank Roger Howe for many valuable discussions on the ideas in this paper.
