# On the prime density of Lucas sequences 

par Pieter MOREE

Résumé. On donne la densité des nombres premiers qui divisent au moins un terme de la suite de Lucas $\left\{L_{n}(P)\right\}_{n=0}^{\infty}$, définie par $L_{0}(P)=2, L_{1}(P)=P$ et $L_{n}(P)=P L_{n-1}(P)+L_{n-2}(P)$ pour $n \geq 2$, avec $P$ entier arbitraire.

Abstract. The density of primes dividing at least one term of the Lucas sequence $\left\{L_{n}(P)\right\}_{n=0}^{\infty}$, defined by $L_{0}(P)=2, L_{1}(P)=$ $P$ and $L_{n}(P)=P L_{n-1}(P)+L_{n-2}(P)$ for $n \geq 2$, with $P$ an arbitrary integer, is determined.

## 1. Introduction

Let $P$ and $Q$ be non-zero integers. Then the sequence defined by

$$
L_{0}(P, Q)=2, \quad L_{1}(P, Q)=P
$$

and for every $n \geq 2, \quad L_{n}(P, Q)=P L_{n-1}(P, Q)-Q L_{n-2}(P, Q)$, is called a Lucas sequence (of the second kind). In this paper we will be mainly concerned with the case $Q=-1$. For convenience we write $L_{n}(P)$ instead of $L_{n}(P,-1)$. If $S$ is any set of primes, then by $S(x)$ we denote the number of elements in $S$ not exceeding $x$. The limit $\lim _{x \rightarrow \infty} S(x) / \pi(x)$, if it exists, is called the prime density of $S$. It will be denoted by $\delta(S)$.

Let $\mathbf{Q}(\sqrt{D})$ be a real quadratic field with $D>1$ and $D$ squarefree. (This assumption on $D$ is maintained throughout.) Let $\mathfrak{O}_{D}$ denote its ring of integers. Suppose $\mathfrak{D}_{D}$ contains a unit of norm -1. (Thus $\epsilon_{D}$, the fundamental unit $>1$, has norm -1.) Let $u \neq \pm 1$ be a unit of $\mathfrak{O}_{D}$. In this paper we are interested in computing the prime density of the set of primes dividing at least one term of the sequence $\left\{u^{n}+\bar{u}^{n}\right\}$. The characteristic polynomial associated to the sequence $\left\{u^{n}+\bar{u}^{n}\right\}$ is irreducible over $\mathbb{Q}$. Few people seem to have considered this problem. The papers $[4,5]$ are the only ones known to the author in this direction. In contrast several authors [ $1,3,6,10$ ] considered the prime density of Lucas sequences of the second kind having reducible characteristic polynomial (i.e. sequences of the form $\left\{a^{n}+b^{n}\right\}$ ).

Our main result is the following.

Theorem 1. Let $D$ be a squarefree integer exceeding 1 such that $\mathbb{Q}(\sqrt{D})$ has a unit of negative norm. Let $u \neq \pm 1$ be a unit. Then there exists $\lambda \geq 0$ and $\epsilon$ of norm -1 such that $u=\epsilon^{2^{\lambda}}$. The sequence $u^{n}+\bar{u}^{n}$ has a prime density. In case $D=2$ it is given by $17 / 24$ if $\lambda=0,5 / 12$ if $\lambda=1$ and $2^{-\lambda} / 3$ otherwise. In case $D>2$ the prime density equals $2^{1-\lambda} / 3$.

It should be remarked that the question whether a quadratic field has a unit of negative norm is still not completely resolved. If $D$ has a prime divisor $p \equiv 3(\bmod 4)$, then there is no such unit. From this it easily follows that there are at most $O(x / \sqrt{\log x})$ discriminants $D \leq x$ for which there is a negative unit. Stevenhagen conjectures that there are asymptotically $c x / \sqrt{\log x}$ such discriminants, for some explict constant $c \approx .58058$. For more on this topic see e.g. [9].

Theorem 1 allows one to compute the density of the Lucas sequence $\left\{L_{n}(P, 1)\right\}$ for various $P$. For example the sequence $\left\{L_{n}(326,1)\right\}$ has density $1 / 3$. More interestingly Theorem 1 allows one to calculate for every integer $P$ the prime density of the Lucas sequence $\left\{L_{n}(P)\right\}$. In this calculation the sequence $\left\{L_{n}(2)\right\}_{n=0}^{\infty}=\{2,2,6,14,34, \cdots\}$, the so called Pell sequence, plays an important rôle.

Theorem 2. For $P$ a non-zero integer let $\left\{L_{n}(P)\right\}_{n=0}^{\infty}$ be the Lucas sequence defined by $L_{0}(P)=2, L_{1}(P)=P$ and, for $n \geq 2, L_{n}(P)=$ $P L_{n-1}(P)+L_{n-2}(P)$. Then the prime density of this sequence exists and equals $2 / 3$, unless $|P|=L_{n}(2)$ for some odd $n \geq 1$, in which case the density is $17 / 24$.

On taking $P=1$ we find that the prime density of the sequence of Lucas numbers equals $2 / 3$. This was first proved by Lagarias [4]. Taking $P=2$ it is seen that the prime density of the Pell sequence is $17 / 24$.

I would like to thank the referee for her/his helpful comments.

## 2. Outline of the proofs

The arithmetic of the sequence $\left\{A_{n}\right\}$, where $A_{n}=\alpha^{n}+\bar{\alpha}^{n}$, and $\alpha \in$ $\mathbb{Q}(\sqrt{D})$ is a quadratic integer, is intimately connected with that of the sequence $\left\{W_{n}\right\}$, where $W_{n}:=\left(\alpha^{n}-\bar{\alpha}^{n}\right) /(\alpha-\bar{\alpha})$. This sequence can be alternatively defined by $W_{0}=0, W_{1}=1, W_{n}=\operatorname{Tr}(\alpha) W_{n-1}-N(\alpha) W_{n-2}$ for $n \geq 2$. It is a Lucas sequence (see [7, p. 41] for a definition) of the first kind. We recall some facts from [7, pp. 41-60]. For primes $p$ with $(p, 2 N(\alpha))=1$, there exists a smallest index $\rho_{\alpha}(p) \geq 1$ such that $p \mid W_{\rho_{\alpha}(p)}$. The index $\rho_{\alpha}(p)$ is called the rank of apparition of $p$ in $\left\{W_{n}\right\}$. If $(p, 2 N(\alpha))=1$, then $p \mid W_{n}$ if and only if $\rho_{\alpha}(p) \mid n$. Furthermore $W_{2 n}=W_{n} A_{n}$ and $\left(W_{n}, A_{n}\right) \mid 2 N(\alpha)^{n}$. Using the latter three properties it can be easily shown that if $(p, 2 N(\alpha))=1$, then $p$ divides $\left\{A_{n}\right\}$ if and only if $\rho_{\alpha}(p)$ is even (cf. [5, Lemma 1]). Indeed our approach to compute the prime
density of $\left\{A_{n}\right\}$ is to compute the density of primes for which $\rho_{\alpha}(p)$ is even. The fact that, for $(p, N(\alpha) \operatorname{Tr}(\alpha) D)=1, \rho_{\alpha}(p)$ divides $p-(D / p)$, forces us to consider the cases $(D / p)=1$ and $(D / p)=-1$ seperately. For $s=1,2, e \geq 0, j \geq 1$ put
$=\left\{p:(p, 2 N(\alpha))=1,\left(\frac{D}{p}\right)=3-2 s, p \equiv 3-2 s+2^{j}\left(\bmod 2^{j+1}\right), 2^{e} \| \rho_{\alpha}(p)\right\}$.
We show that $N_{1}(e, j ; \alpha)$ has a prime density, $\delta_{1}(e, j ; \alpha)$, and express it in terms of degrees of certain Kummerian extensions. This approach goes back to Hasse [3]. The case $s=2$ is rather more difficult, except when $\alpha$ is a unit of negative norm, in which case even elementary arguments suffice. So assume $\alpha=\epsilon$ is a quadratic unit of norm -1. In this case it is not difficult to show that the prime density of the sequence $\left\{A_{n}\right\}=\left\{L_{n}(\operatorname{Tr}(\epsilon))\right\}$ is given by

$$
1-\sum_{j=1}^{\infty}\left\{\delta_{1}(0, j ; \epsilon)+\delta_{2}(0, j ; \epsilon)\right\}
$$

The prime densities $\delta_{1}(e, j ; \epsilon)$ and $\delta_{2}(e, j ; \epsilon)$ are computed in respectively $\S 3$ and $\S 4$. They are tabulated in Tables I and II. The entry $e$ in the last column gives $\sum_{j=1}^{\infty} \delta_{s}(e, j ; \epsilon)$. The entry $j$ in the last row gives $\sum_{e=0}^{\infty} \delta_{s}(e, j ; \epsilon)$. The distinction between the case $D=2$ and $D>2$ is due to the fact that for $D \geq 2, \mathbb{Q}(\sqrt{D})$ is only a subfield of $\mathbb{Q}\left(\zeta_{2^{j}}\right)$ for some $j$ if $D=2$. Finally in $\S 5$ proofs of Theorems 1 and 2 are given.

## 3. The prime divisors of Lucas sequences splitting in the associated quadratic number field

Let $\alpha \in \mathbb{Q}(\sqrt{D}) \backslash \mathbb{Q}$ be a quadratic integer. In this section the prime density, $\delta_{1}(e, j ; \alpha)$, of the set $N_{1}(e, j ; \alpha)$ will be computed by relating it to the degrees of certain finite extensions of $\mathbb{Q}$ (Lemma 1). In Lemma 3 these degrees are then computed in case $N(\alpha)=-1$. Using Lemma 1 and Lemma 3 one easily arrives at Table I. 1 and II.1. The fact that the second column in Table I. 1 only contains zero entries is due to the fact that there are no primes satisfying $(2 / p)=1$ and $p \equiv 5(\bmod 8)$.
Lemma 1. Let $\alpha \in \mathbb{Q}(\sqrt{D}) \backslash \mathbb{Q}$ be a quadratic integer. Put $\theta=\alpha^{2} / N(\alpha)$. For $0 \leq r \leq s$ put $K_{r, s}=\mathbf{Q}\left(\sqrt{D}, \theta^{1 / 2^{r}}, \zeta_{2^{s}}\right)$. Let $d_{r, s}=\left[K_{r, s}: \mathbb{Q}\right]$. Let $j \geq 1$ and $0 \leq e \leq j$. Then the prime density, $\delta_{1}(e, j ; \alpha)$, of

$$
\begin{gathered}
N_{1}(e, j ; \alpha):= \\
:=\left\{p:(p, 2 N(\alpha))=1,\left(\frac{D}{p}\right)=1, p \equiv 1+2^{j}\left(\bmod 2^{j+1}\right), 2^{e} \| \rho_{\alpha}(p)\right\}
\end{gathered}
$$

exists. In case $e=0$,

$$
\delta_{1}(0, j ; \alpha)=\frac{1}{d_{j, j}}-\frac{1}{d_{j, j+1}}
$$

In case $e \geq 1$,

$$
\delta_{1}(e, j ; \alpha)=\frac{1}{d_{j-e, j}}-\frac{1}{d_{j-e, j+1}}-\frac{1}{d_{j-e+1, j}}+\frac{1}{d_{j-e+1, j+1}}
$$

Furthermore $\delta_{1}(e, j ; \alpha)=0$ in case $e>j$.
Proof. Some details of the proof will be surpressed. The reader having difficulties supplying the missing details is referred to [5]. If $(D / p)=1$ then $p$ splits in $\mathbb{Q}(\sqrt{D})$. So $(p)=\mathfrak{P} \overline{\mathfrak{P}}$ in $\mathfrak{O}_{D}$. If $(p, 2 N(\alpha))=1$, then $\operatorname{ord}_{\mathfrak{P}}(\theta)=\operatorname{ord}_{\mathfrak{P}}(\theta)=\rho_{\alpha}(p)$. Using that for all large enough primes satisfying $(D / p)=1, \rho_{\alpha}(p) \mid p-1$, it follows that $N_{1}(e, j ; \alpha)$ is finite in case $e>j$. Then $\delta_{1}(e, j ; \alpha)=0$. Now assume $e \leq j$. Let $\sigma_{\alpha}(p)$ denote the exact power of 2 dividing $\rho_{\alpha}(p)$. Put

$$
S_{j}=\left\{p:(p, 2 N(\alpha))=1,\left(\frac{D}{p}\right)=1, p \equiv 1+2^{j}\left(\bmod 2^{j+1}\right)\right\}
$$

Then the set $N_{1}(e, j ; \alpha)$ equals

$$
\left\{p: p \in S_{j}, \sigma_{\alpha}(p) \mid 2^{e}\right\} \backslash\left\{p: p \in S_{j}, \sigma_{\alpha}(p) \mid 2^{e-1}\right\}
$$

This, on its turn, can be written as $\left\{p: p \in S_{j}, \theta^{\frac{p-1}{2 j}} \equiv 1(\bmod \mathfrak{P})\right\}$ if $e=0$ and

$$
\left\{p: p \in S_{j}, \theta^{\frac{p-1}{2^{j-e}}} \equiv 1(\bmod \mathfrak{P})\right\} \backslash\left\{p: p \in S_{j}, \theta^{\frac{p-1}{2^{j-e+1}}} \equiv 1(\bmod \mathfrak{P})\right\}
$$

otherwise. The latter set equals

$$
\left\{p:(p, 2 N(\alpha))=1,\left(\frac{D}{p}\right)=1, p \equiv 1\left(\bmod 2^{j}\right), \theta^{\left.\frac{p-1}{2^{j-\epsilon+1}} \equiv 1(\bmod \mathfrak{P})\right\}, ~}\right.
$$

with the subset

$$
\left\{p:(p, 2 N(\alpha))=1,\left(\frac{D}{p}\right)=1, p \equiv 1\left(\bmod 2^{j+1}\right), \theta^{\frac{p-1}{2^{j-e+1}}} \equiv 1(\bmod \mathfrak{P})\right\}
$$

taken out. The latter set equals, with at most finitely many exceptions, the set of primes that split completely in $K_{j-e+1, j+1}$. Since for $r \leq s, K_{r, s}$ is normal over $\mathbb{Q}$, it follows by the prime ideal theorem or by the Chebotarev density theorem that the prime density of this set equals $d_{j-e+1, j+1}^{-1}$. The density of the other sets involved are computed similarly. One finds $\delta_{1}(0, j ; \alpha)=d_{j, j}^{-1}-d_{j, j+1}^{-1}$ and, in the case $e \geq 1, \delta_{1}(e, j ; \alpha)=d_{j-e, j}^{-1}-$ $d_{j-e, j+1}^{-1}-d_{j-e+1, j}^{-1}+d_{j-e+1, j+1}^{-1}$.

In our computation of the degrees $d_{a, b}$ we will make use of the following easy lemma.

Lemma 2. [2, Satz 1]
The field $\mathbb{Q}(\sqrt{\alpha})$ with $\alpha \in \mathbb{Q}(\sqrt{D}) \backslash \mathbb{Q}$ is normal over $\mathbb{Q}$ if and only if $N(\alpha)$ is a square in $\mathbb{Q}(\sqrt{D})$.

Lemma 3. Suppose that $\epsilon>0$ is a unit of negative norm in $\mathcal{O}_{D}$.
(i) $D=2$. We have $d_{0,1}=2, d_{0,2}=4$ and $d_{0, b}=2^{b-1}$ for $b \geq 3$. Furthermore $d_{1,1}=4, d_{1, b}=d_{0, b}$ for $b \geq 2$. For $b>a \geq 2, d_{a, b}=2^{a+b-2}$. Finally, $d_{2,2}=8$ and $d_{j, j}=2^{2 j-2}$ for $j \geq 3$.
(ii) $D>2$. We have for $b>a \geq 1, d_{a, b}=2^{a+b-1}$. Furthermore $d_{0, b}=$ $2^{b}, b \geq 1, d_{1,1}=4$ and $d_{b, b}=2^{2 b-1}$ for $b \geq 2$.
Proof. (i). Since $\sqrt{2} \in \mathbb{Q}\left(\zeta_{8}\right)$, we have, for $b \geq 3, \mathbb{Q}\left(\sqrt{2}, \zeta_{2^{b}}\right)=\mathbb{Q}\left(\zeta_{2^{b}}\right)$ and thus $d_{0, b}=2^{b-1}$. For $a=1, b \geq 2$ we have $\mathbb{Q}\left(\sqrt{2}, \sqrt{-\alpha^{2}}, \zeta_{2^{b}}\right)=$ $\mathbb{Q}\left(\sqrt{2}, i, \zeta_{2^{b}}\right)=\mathbb{Q}\left(\sqrt{2}, \zeta_{2^{b}}\right)$. Thus $d_{1, b}=d_{0, b}$ for $b \geq 2$. Now assume that $b>$ $a \geq 2$. Then $\mathbb{Q}\left(\sqrt{2},\left(-\alpha^{2}\right)^{1 / 2^{a}}, \zeta_{2^{b}}\right)=\mathbb{Q}\left(\sqrt{2}, \alpha^{1 / 2^{a-1}}, \zeta_{2^{b}}\right)=\mathbb{Q}\left(\alpha^{1 / 2^{a-1}}, \zeta_{2^{b}}\right)$. I claim that $x^{2^{a-1}}-\alpha$ is irreducible over $\mathbb{Q}\left(\zeta_{2^{b}}\right)$. If it were not, then $\mathbb{Q}(\sqrt{\alpha})$ would be a subfield of $\mathbb{Q}\left(\zeta_{2^{b}}\right)$ and hence normal. But since $\mathbb{Q}(\sqrt{\alpha})$ is not normal by Lemma 2, this is impossible. Thus $\left[\mathbb{Q}\left(\alpha^{1 / 2^{a-1}}, \zeta_{2^{b}}\right): \mathbb{Q}\right]=\left[\mathcal{Q}\left(\alpha^{1 / 2^{a-1}}:\right.\right.$ $\left.\mathbb{Q}\left(\zeta_{2^{b}}\right)\right]\left[\mathbb{Q}\left(\zeta_{2^{b}}\right): \mathbb{Q}\right]=2^{a+b-2}$. Next consider the field $\mathbb{Q}\left(\sqrt{2},\left(-\alpha^{2}\right)^{1 / 2^{b}}, \zeta_{2^{b}}\right)$ for $b \geq 3$. Note that

$$
\mathbf{Q}\left(\sqrt{2},\left(-\alpha^{2}\right)^{1 / 2^{b}}, \zeta_{2^{b}}\right)=\mathbf{Q}\left(\sqrt{2}, \alpha^{1 / 2^{b-2}}, \zeta_{2^{b}}, \sqrt{\alpha^{1 / 2^{b-2}} \zeta_{2^{b}}}\right)
$$

By taking composita with $\mathbb{Q}\left(\zeta_{2^{b+1}}\right)$ one sees that

$$
r:=\left[\mathbb{Q}\left(\sqrt{2}, \alpha^{1 / 2^{b-2}}, \zeta_{2^{b}}, \sqrt{\alpha^{1 / 2^{b-2}} \zeta_{2^{b}}}\right): \mathbb{Q}\left(\sqrt{2}, \alpha^{1 / 2^{b-2}}, \zeta_{2^{b}}\right)\right]=2 .
$$

Thus $d_{b, b}=r d_{b-1, b}=2^{2 b-2}$. Finally one checks that the missing degrees, $d_{0,1}, d_{0,2}, d_{1,1}$ and $d_{2,2}$, are as asserted.
(ii). We only deal with the case $b>a \geq 2$. The other cases are even more similar to (i) and left to the reader (see also [5, Lemma 6]). We have $\mathbb{Q}\left(\sqrt{D},\left(-\alpha^{2}\right)^{1 / 2^{a}}, \zeta_{2^{b}}\right)=\mathbb{Q}\left(\sqrt{D}, \alpha^{1 / 2^{a-1}}, \zeta_{2^{b}}\right)$. I claim that $X^{2^{a-1}}-\alpha$ is irreducible over $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{b}}\right)$. Note that the latter field, as a compositum of two abelian fields, is itself abelian. Hence all its subfields are normal. Now if $X^{2^{a-1}}-\alpha$ were reducible over $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{b}}\right), \mathbb{Q}(\sqrt{\alpha})$ would be a subfield of $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{b}}\right)$. By Lemma 2 this is seen to be impossible. The degree $d_{a, b}$ is then computed as in (i).

## 4. The prime divisors of Lucas sequences inert in the associated quadratic number field

As will be seen, in case $\alpha$ is a unit of negative norm, the problem of computing the density $\delta_{2}(e, j ; \alpha)$ can be easily reduced to that of computing the density of $\left\{p:(D / p)=-1, p \equiv-1+2^{j}\left(\bmod 2^{j+1}\right)\right\}$. For $D>2$ this density is computed in the next lemma.

Lemma 4. Let $D>2$ be squarefree. For $s=1,2$ and $j \geq 1$ put

$$
R_{s, j}=\left\{p:\left(\frac{D}{p}\right)=3-2 s, p \equiv-1+2^{j}\left(\bmod 2^{j+1}\right)\right\}
$$

Then $\delta\left(R_{s, j}\right)$, the prime density of $R_{s, j}$, equals $2^{-1-j}$.
Proof. Consider the set of primes

$$
V_{j}:=\left\{p:\left(\frac{D}{p}\right)=1, p \equiv-1\left(\bmod 2^{j}\right)\right\}
$$

Let $j \geq 2$. Now $(D / p)=1$ and $p \equiv \pm 1\left(\bmod 2^{j}\right)$ if and only if the prime $p$ splits completely in $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}+\zeta_{2^{j}}^{-1}\right)$. Similarly $(D / p)=1$ and $p \equiv$ $-1\left(\bmod 2^{j}\right)$ if and only if $p$ splits completely in $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}+\zeta_{2^{j}}^{-1}\right)$ but does not split completely in $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}\right)$. Since both of these number fields are normal extensions of $\mathbb{Q}$, it follows by the Chebotarev density theorem that

$$
\delta\left(S_{j}\right)=\frac{1}{\left[Q\left(\sqrt{D}, \zeta_{2^{j}}+\zeta_{2^{j}}^{-1}\right): \mathbb{Q}\right]}-\frac{1}{\left[\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}\right): \mathbb{Q}\right]}
$$

Since $\left[\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}\right): \mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}+\zeta_{2^{j}}^{-1}\right)\right] \mid 2$ and $\left.\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}+\zeta_{2^{j}}^{-1}\right)\right)$ as a totally real field is strictly included in $\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}\right)$, it follows that $\delta\left(V_{j}\right)=$ $\left[\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}\right): \mathbb{Q}\right]^{-1}$. Since the only real quadratic subfield of $\mathbb{Q}\left(\zeta_{2^{j}}\right)$ is at most $\mathbb{Q}(\sqrt{2})$, it follows that $\left[\mathbb{Q}\left(\sqrt{D}, \zeta_{2^{j}}\right): \mathbb{Q}\right]=[\mathbb{Q}(\sqrt{D}): \mathbb{Q}]\left[\mathbb{Q}\left(\zeta_{2^{j}}\right): \mathbb{Q}\right]=2^{j}$ and hence $\delta\left(V_{j}\right)=2^{-j}$. Now notice that $R_{1, j}=V_{j} \backslash V_{j+1}$. Thus $\delta\left(R_{1, j}\right)=$ $\delta\left(V_{j}\right)-\delta\left(V_{j+1}\right)=2^{-1-j}$. If $j=1$ then note that $S_{1}$ is the set of primes that split completely in the normal field $\mathbb{Q}(\sqrt{D}, i)$. Thus

$$
\delta\left(R_{1,1}\right)=\frac{1}{[\mathbb{Q}(\sqrt{D}, i): \mathbb{Q}]}=\frac{1}{4}
$$

The case $s=2$ is almost immediate now.
Remark. From the law of quadratic reciprocity one deduces that for odd $D,(D / p)=1$ if and only if $p \equiv \pm \beta(\bmod 4 D)$ for a set of odd $\beta$ (this result was already conjectured by Euler). This set has $\varphi(D) / 2$ elements. Using this, the supplementary law of quadratic reciprocity, the chinese remainder theorem and the prime number theorem for arithmetic progressions, one can give an alternative proof of Lemma 4.

Let $\epsilon$ be a unit of negative norm. Now we are in the position to compute $\delta_{2}(e, j ; \epsilon)$. For primes inert in $\mathbb{Q}(\sqrt{D}), \mathbb{Z}[\epsilon] /(p) \cong \mathrm{F}_{p^{2}}$, and hence the Frobenius map acts by conjugation on $\epsilon$, that is $\epsilon^{p} \equiv \bar{\epsilon}(\bmod (p))$. Thus, since $N(\epsilon)=-1$, we have $\epsilon^{p+1} \equiv-1(\bmod (p))$. Hence if $p \equiv$ $-1+2^{j}\left(\bmod 2^{j+1}\right), j \geq 2$, then $\theta^{\frac{p+1}{2}}=(-1)^{\frac{p+1}{2}} \epsilon^{p+1} \equiv-1(\bmod (p))$. Thus $2^{j} \| \operatorname{ord}_{(p)}(\theta)\left(=\rho_{\epsilon}(p)\right)$ and therefore $N_{2}(j, j ; \epsilon)=\{p:(D / p)=-1, p \equiv$
$\left.-1+2^{j}\left(\bmod 2^{j+1}\right)\right\}$. In the case $D>2, j \geq 2, \delta_{2}(j, j ; \epsilon)=2^{-j-1}$, by Lemma 4. If $D=2$, then $\delta_{2}(j, j ; \epsilon)=0$ for $j \geq 3$ and $N_{2}(2,2 ; \epsilon)=\{p: p \equiv$ $3(\bmod 8)\}$, that is $\delta_{2}(2,2 ; \epsilon)=1 / 4$. In case $j=1, p \equiv 1(\bmod 4)$ and so $\theta^{\frac{p+1}{2}}=(-1)^{\frac{p+1}{2}} \epsilon^{p+1} \equiv 1(\bmod (p))$. Since $(p+1) / 2$ is odd, $N_{2}(0,1 ; \epsilon)=$ $\{p:(D / p)=-1, p \equiv 1(\bmod 4)\}$. If $D>2$, then $\delta_{2}(0,1 ; \epsilon)=1 / 4$ by Lemma 4. If $D=2$ then $N_{2}(0,1 ; \epsilon)=\{p: p \equiv 5(\bmod 8)\}$ and so again $\delta_{2}(0,1 ; \epsilon)=1 / 4$. Thus we arrive at Table I. 2 and Table II.2.

## 5. Proofs of Theorems 1 and 2

Theorem 1 is easily deduced from the following theorem.
Theorem 3. Let $\epsilon$ be a unit of negative norm in $\mathcal{O}_{D}$. Let $\rho_{\epsilon}(p)$ denote the rank of apparition of $p$ in the sequence $\left\{\epsilon^{n}+\bar{\epsilon}^{n}\right\}$. Consider for $e \geq 0$ the prime density, $\delta(e ; \epsilon)$, of the set $\left\{p: 2^{e} \| \rho_{\epsilon}(p)\right\}$. In case $D=2$ it equals $7 / 24$ if $e \leq 1,1 / 3$ if $e=2$ and $2^{-e} / 3$ for $e \geq 3$. In case $D>2$ it equals $1 / 3$ if $e=0$ and $2^{1-e} / 3$ if $e \geq 1$.
Proof. Let $N(e, \epsilon)=\left\{p: 2^{e} \| \rho_{\epsilon}(p)\right\}$ and for $s=1,2$ let

$$
N_{s}(e ; \epsilon)=\left\{p:\left(\frac{D}{p}\right)=3-2 s, 2^{e} \| \rho_{\epsilon}(p)\right\} .
$$

Let $\delta_{s}(e ; \epsilon)$ denote the prime density of $N_{s}(e ; \epsilon)$. Thus, with at most finitely many exceptions, $N(e ; \epsilon)=N_{1}(e ; \epsilon) \cup N_{2}(e ; \epsilon)$. Now $N_{1}(e ; \epsilon)=\cup_{j=1}^{\infty} N_{1}(e, j ; \epsilon)$ and $N_{2}(e ; \epsilon)=\cup_{j=1}^{\infty} N_{2}(e, j ; \epsilon)$. Since the latter is a finite disjoint union of sets of non-zero density, we have $\delta_{2}(e ; \epsilon)=\sum_{j=1}^{\infty} \delta_{2}(e, j ; \epsilon)$. Similarly we want to show that $\delta_{1}(e ; \epsilon)=\sum_{j=1}^{\infty} \delta_{1}(e, j ; \epsilon)$. As $\cup_{j=1}^{\infty} N_{1}(e, j ; \epsilon)$ is an infinite union of sets of non-zero density, this needs proof. We proceed as in [4, p. 454]. Put

$$
C_{1}(e, j ; \epsilon)=\left\{p:\left(\frac{D}{p}\right)=1, p \equiv 1+2^{j}\left(\bmod 2^{j+1}\right) \text { and } p \notin N_{1}(e, j, \epsilon)\right\} .
$$

Using Lemma 4 the density of this set is seen to be $2^{-j}-\delta_{1}(e, j ; \epsilon)$ in case $D=2$ and $j \geq 3$, and $2^{-1-j}-\delta_{1}(e, j ; \epsilon)$ in case $D>2$. Now

$$
\cup_{j=1}^{m} N_{1}(e, j ; \epsilon) \subseteq N_{1}(e ; \epsilon) \subseteq\left\{p:\left(\frac{D}{p}\right)=1\right\} \backslash \cup_{j=1}^{m} C_{1}(e, j ; \epsilon)
$$

The smallest set in the above inclusion of sets has density $\sum_{j=1}^{m} \delta_{1}(e, j ; \epsilon)$. The largest set has prime density $2^{-m}+\sum_{j=1}^{m} \delta_{1}(e, j ; \epsilon)$ in case $D=2$ and $m \geq 3$, and prime density $2^{-1-m}+\sum_{j=1}^{m} \delta_{1}(e, j ; \epsilon)$ in case $D>2$. Letting $m \rightarrow \infty$ shows that $\delta_{1}(e ; \epsilon)=\sum_{j=1}^{\infty} \delta_{1}(e, j ; \epsilon)$. On computing the densities $\sum_{j=1}^{\infty}\left\{\delta_{1}(e, j ; \epsilon)+\delta_{2}(e, j ; \epsilon)\right\}$, on making use of Lemma 1 and Lemma 3, the proof is then completed.
Proof of Theorem 1. Since the prime density of $\left\{u^{n}+\bar{u}^{n}\right\}$ is invariant
under replacing $u$ by $\bar{u},-u$ or $-\bar{u}$ and, by assumption, $u \neq \pm 1$, we may assume w.l.o.g. that $u>1$. Then $u=\epsilon_{D}^{N}$ for some $N>1$, where $\epsilon_{D}$ is the fundamental unit of $\mathrm{Q}(\sqrt{D})$. Write $N=2^{\lambda} m$ with $m$ odd. Put $\epsilon=\epsilon_{D}^{m}$. Then $u=\epsilon^{2^{\lambda}}$ with $N(\epsilon)=-1$. Note that $\lambda$ is unique. Consider the sequence $\left\{u^{n}+\bar{u}^{n}\right\}$ as a subsequence of $\left\{\epsilon^{n}+\bar{\epsilon}^{n}\right\}$. One easily shows that $p$ divides $\left\{\epsilon^{2^{\lambda} n}+\bar{\epsilon}^{2^{\lambda} n}\right\}$ if and only if $\rho_{\epsilon}(p)$ is divisible by $2^{\lambda+1}$. Hence the prime density of $\left\{u^{n}+\bar{u}^{n}\right\}$ equals

$$
1-\sum_{m=0}^{\lambda} \delta\left(\left\{p: 2^{m} \| \rho_{\epsilon}(p)\right\}\right)
$$

Using this expression and Theorem 3, Theorem 1 follows.
Proof of Theorem 2. Put $D=P^{2}+4$. Notice that for $P \neq 0, D$ is not a square. We have $L_{n}(P)=\alpha^{n}+\bar{\alpha}^{n}$ with $\alpha=(P+\sqrt{D}) / 2$. If $D \equiv 0(\bmod 4)$ then $\alpha \in \mathbb{Z}[\sqrt{D}]$, if $D \equiv 1(\bmod 4)$ then $\alpha \in \mathbb{Z}[(1+\sqrt{D}) / 2]$. Thus $\alpha \in \mathfrak{D}_{D}$. Furthermore $N(\alpha)=-1$. In order to apply Theorem 1 we have to determine when $\mathbb{Q}\left(\sqrt{P^{2}+4}\right)=\mathbb{Q}(\sqrt{2})$, that is we have to find all solutions $P$ to the Pell equation $P^{2}-2 Q^{2}=-4$. The fundamental unit of $Q(\sqrt{2})$ is $1+\sqrt{2}$. By the theory of Pell equations it follows that the solutions $(P, Q) \in \mathbb{Z}_{\geq 0}^{2}$ of $P^{2}-2 Q^{2}=-4$ are precisely given by $\left\{\left(x_{n}, y_{n}\right): n \geq 1\right.$ is odd $\}$, where $x_{n}+y_{n} \sqrt{2}=2(1+\sqrt{2})^{n}$. Noting that

$$
2(1+\sqrt{2})^{n}=(1+\sqrt{2})^{n}+(1-\sqrt{2})^{n}+\left(\frac{(1+\sqrt{2})^{n}-(1-\sqrt{2})^{n}}{\sqrt{2}}\right) \sqrt{2}
$$

it is seen that $x_{n}=L_{n}(2)$. Theorem 2 now follows on invoking Theorem 1.

With the previous proof in mind the reader will have few problems in proving the following curiosum.

Theorem 4. Let $D>1$ be squarefree. Suppose that $X^{2}-D Y^{2}=-4$ has a solution. For $s=1,2$, let $\mathcal{C}_{s}$ denote the set of prime divisors of the set

$$
\mathcal{W}_{s}:=\left\{P \in \mathbb{N}: P^{2}-D Q^{2}=(-1)^{s} 4 \text { for some } Q \in \mathbb{Z}\right\}
$$

and $\mathcal{C}_{2+s}$ the set of prime divisors of the set

$$
\mathcal{W}_{2+s}:=\left\{Q \in \mathbb{N}: P^{2}-D Q^{2}=(-1)^{s} 4 \text { for some } P \in \mathbb{Z}\right\}
$$

One has $\delta\left(\mathcal{C}_{4}\right)=1$. Furthermore, when $D=2, \delta\left(\mathcal{C}_{1}\right)=7 / 24, \delta\left(\mathcal{C}_{2}\right)=5 / 12$ and $\delta\left(\mathcal{C}_{3}\right)=7 / 24$. If $D>2$, then $\delta\left(\mathcal{C}_{j}\right)=1 / 3$ for $1 \leq j \leq 3$.

Proof. If $x^{2}-D y^{2}=-4$ has a solution, then $N\left(\epsilon_{D}\right)=-1$. Define sequences of integers $\left\{x_{n}\right\}$ and $\left\{y_{n}\right\}$ by $x_{n}+y_{n} \sqrt{D}=2 \epsilon_{D}^{n}$. Then, see [8, p. 65], $\mathcal{W}_{1}=\left\{x_{n}: n \geq 1\right.$ is odd $\}, \mathcal{W}_{2}=\left\{x_{n}: n \geq 1\right.$ is even $\}, \mathcal{W}_{3}=\left\{y_{n}:\right.$ $n \geq 1$ is odd $\}$, and $\mathcal{W}_{4}=\left\{y_{n}: n \geq 1\right.$ is even $\}$. Notice that $x_{n}=\epsilon_{D}^{n}+\bar{\epsilon}_{D}^{n}$ and $y_{n}=\left(\epsilon_{D}^{n}-\bar{\epsilon}_{D}^{n}\right) / \sqrt{D}$. Using this, one easily sees that $\delta\left(\mathcal{C}_{1}\right)=\delta\left(1 ; \epsilon_{D}\right)$, $\delta\left(\mathcal{C}_{2}\right)=1-\delta\left(0 ; \epsilon_{D}\right)-\delta\left(1 ; \epsilon_{D}\right), \delta\left(\mathcal{C}_{3}\right)=\delta\left(0 ; \epsilon_{D}\right)$ and $\delta\left(\mathcal{C}_{4}\right)=1$. The result now follows from Theorem 3.
